Only experiments will validate your computational models !

Understanding Ligand Binding

- The most crucial question in early drug discovery
 - Hit identification
 - Hit to lead expansion
 - Lead optimisation

The Important Questions

Data Analysis ...

- Which molecule(s) to choose for biological assessment ?
- How to modify molecules for optimising properties ?
- How to build models for reliable medicinal chemistry decision support ?
- How to design molecules void of toxicity risks ?

... and Representation

- How to guide analysis of molecular modelling results ?
- How to make use of MD trajectories for molecular design ?

A Possible Way To Do It

- Compare compound structures in view of their preferences for specific molecular interactions
- Annotate molecules with all interaction features possible
- Find out, which of them are the really important ones ...

Target Structure Available

- Consider only all those interactions of the ligand within the protein binding site

Schütz D., PhD Thesis,
University of Vienna, 2018

The Pharmacophore Concept

“A pharmacophore is the ensemble of steric and electronic features that is necessary to ensure optimal supra-molecular interactions of a ligand with a specific biological target and to trigger (or block) its biological response.”

1933 - 2015

C.-G. Wermuth et al., Pure Appl. Chem. 1998, 70: 1129-1143

Feature-based Pharmacophores

Totality of universal chemical features that represent a defined binding mode of a ligand to a bio-molecular target

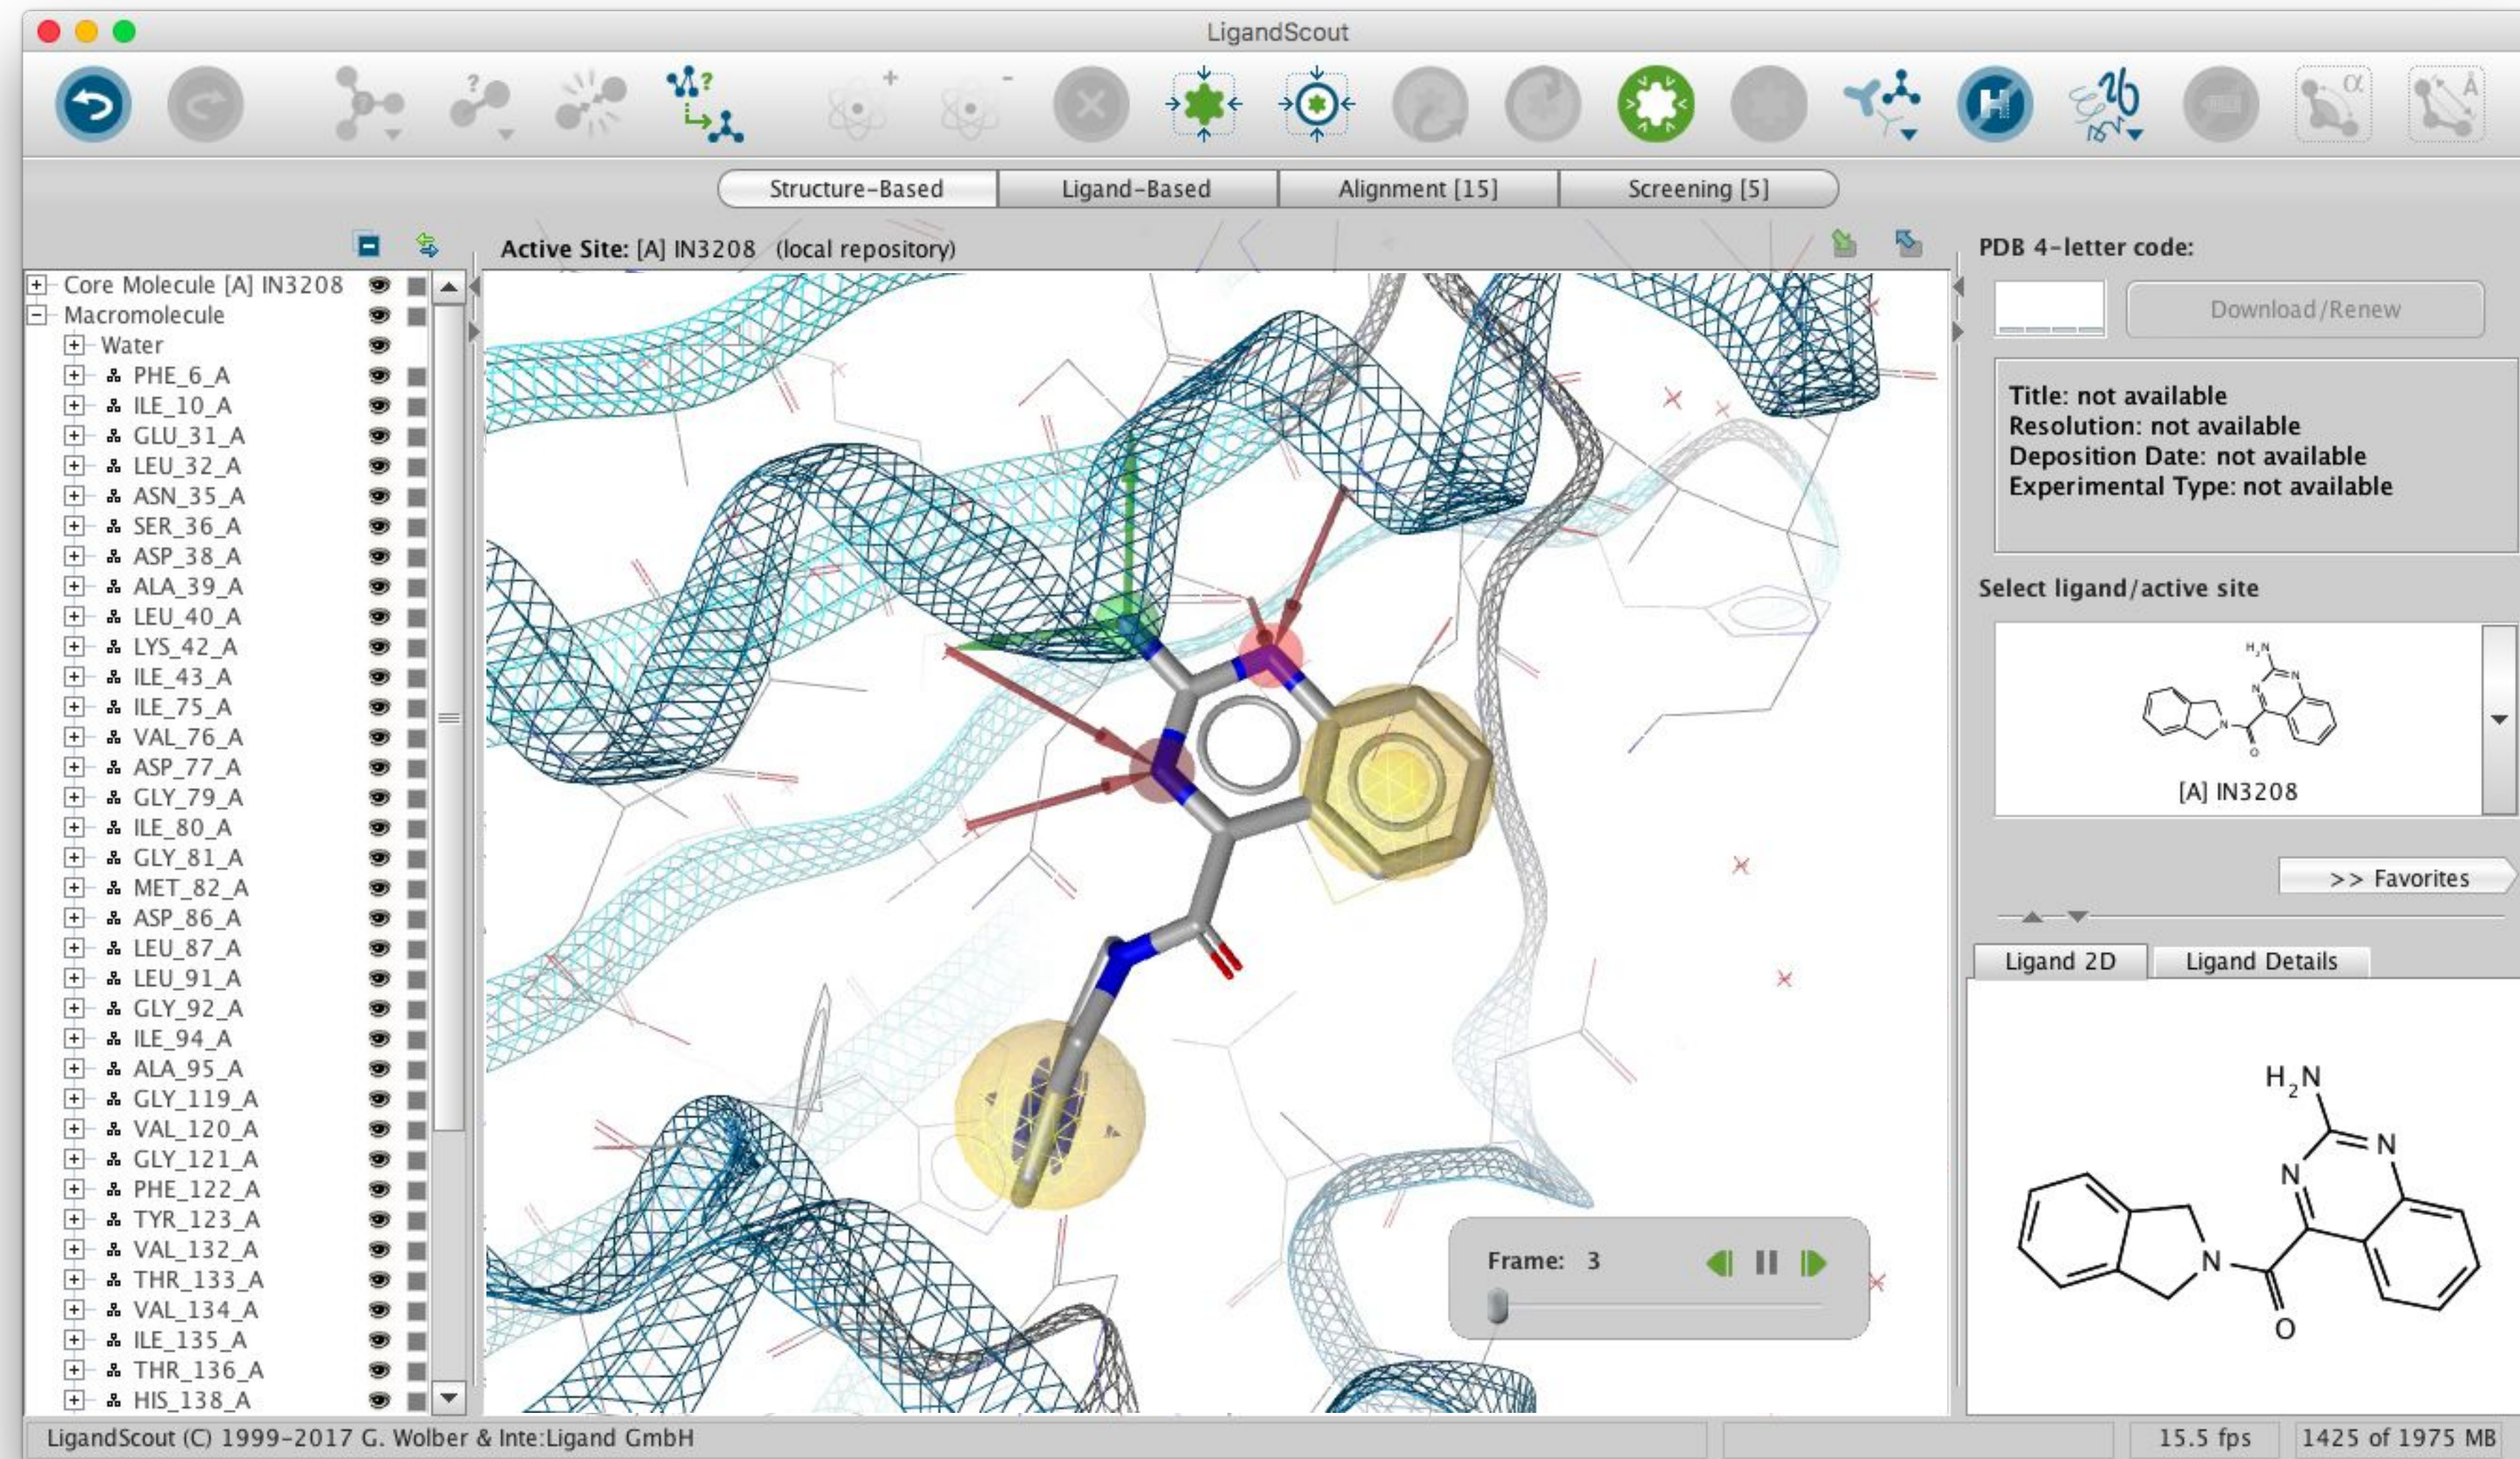

Features: Electrostatic interactions, H-bonding, aromatic interactions, hydrophobic regions, coordination to metal ions, halogen bonds ...

A pharmacophore model is the most suitable data representation method for guiding medicinal chemistry

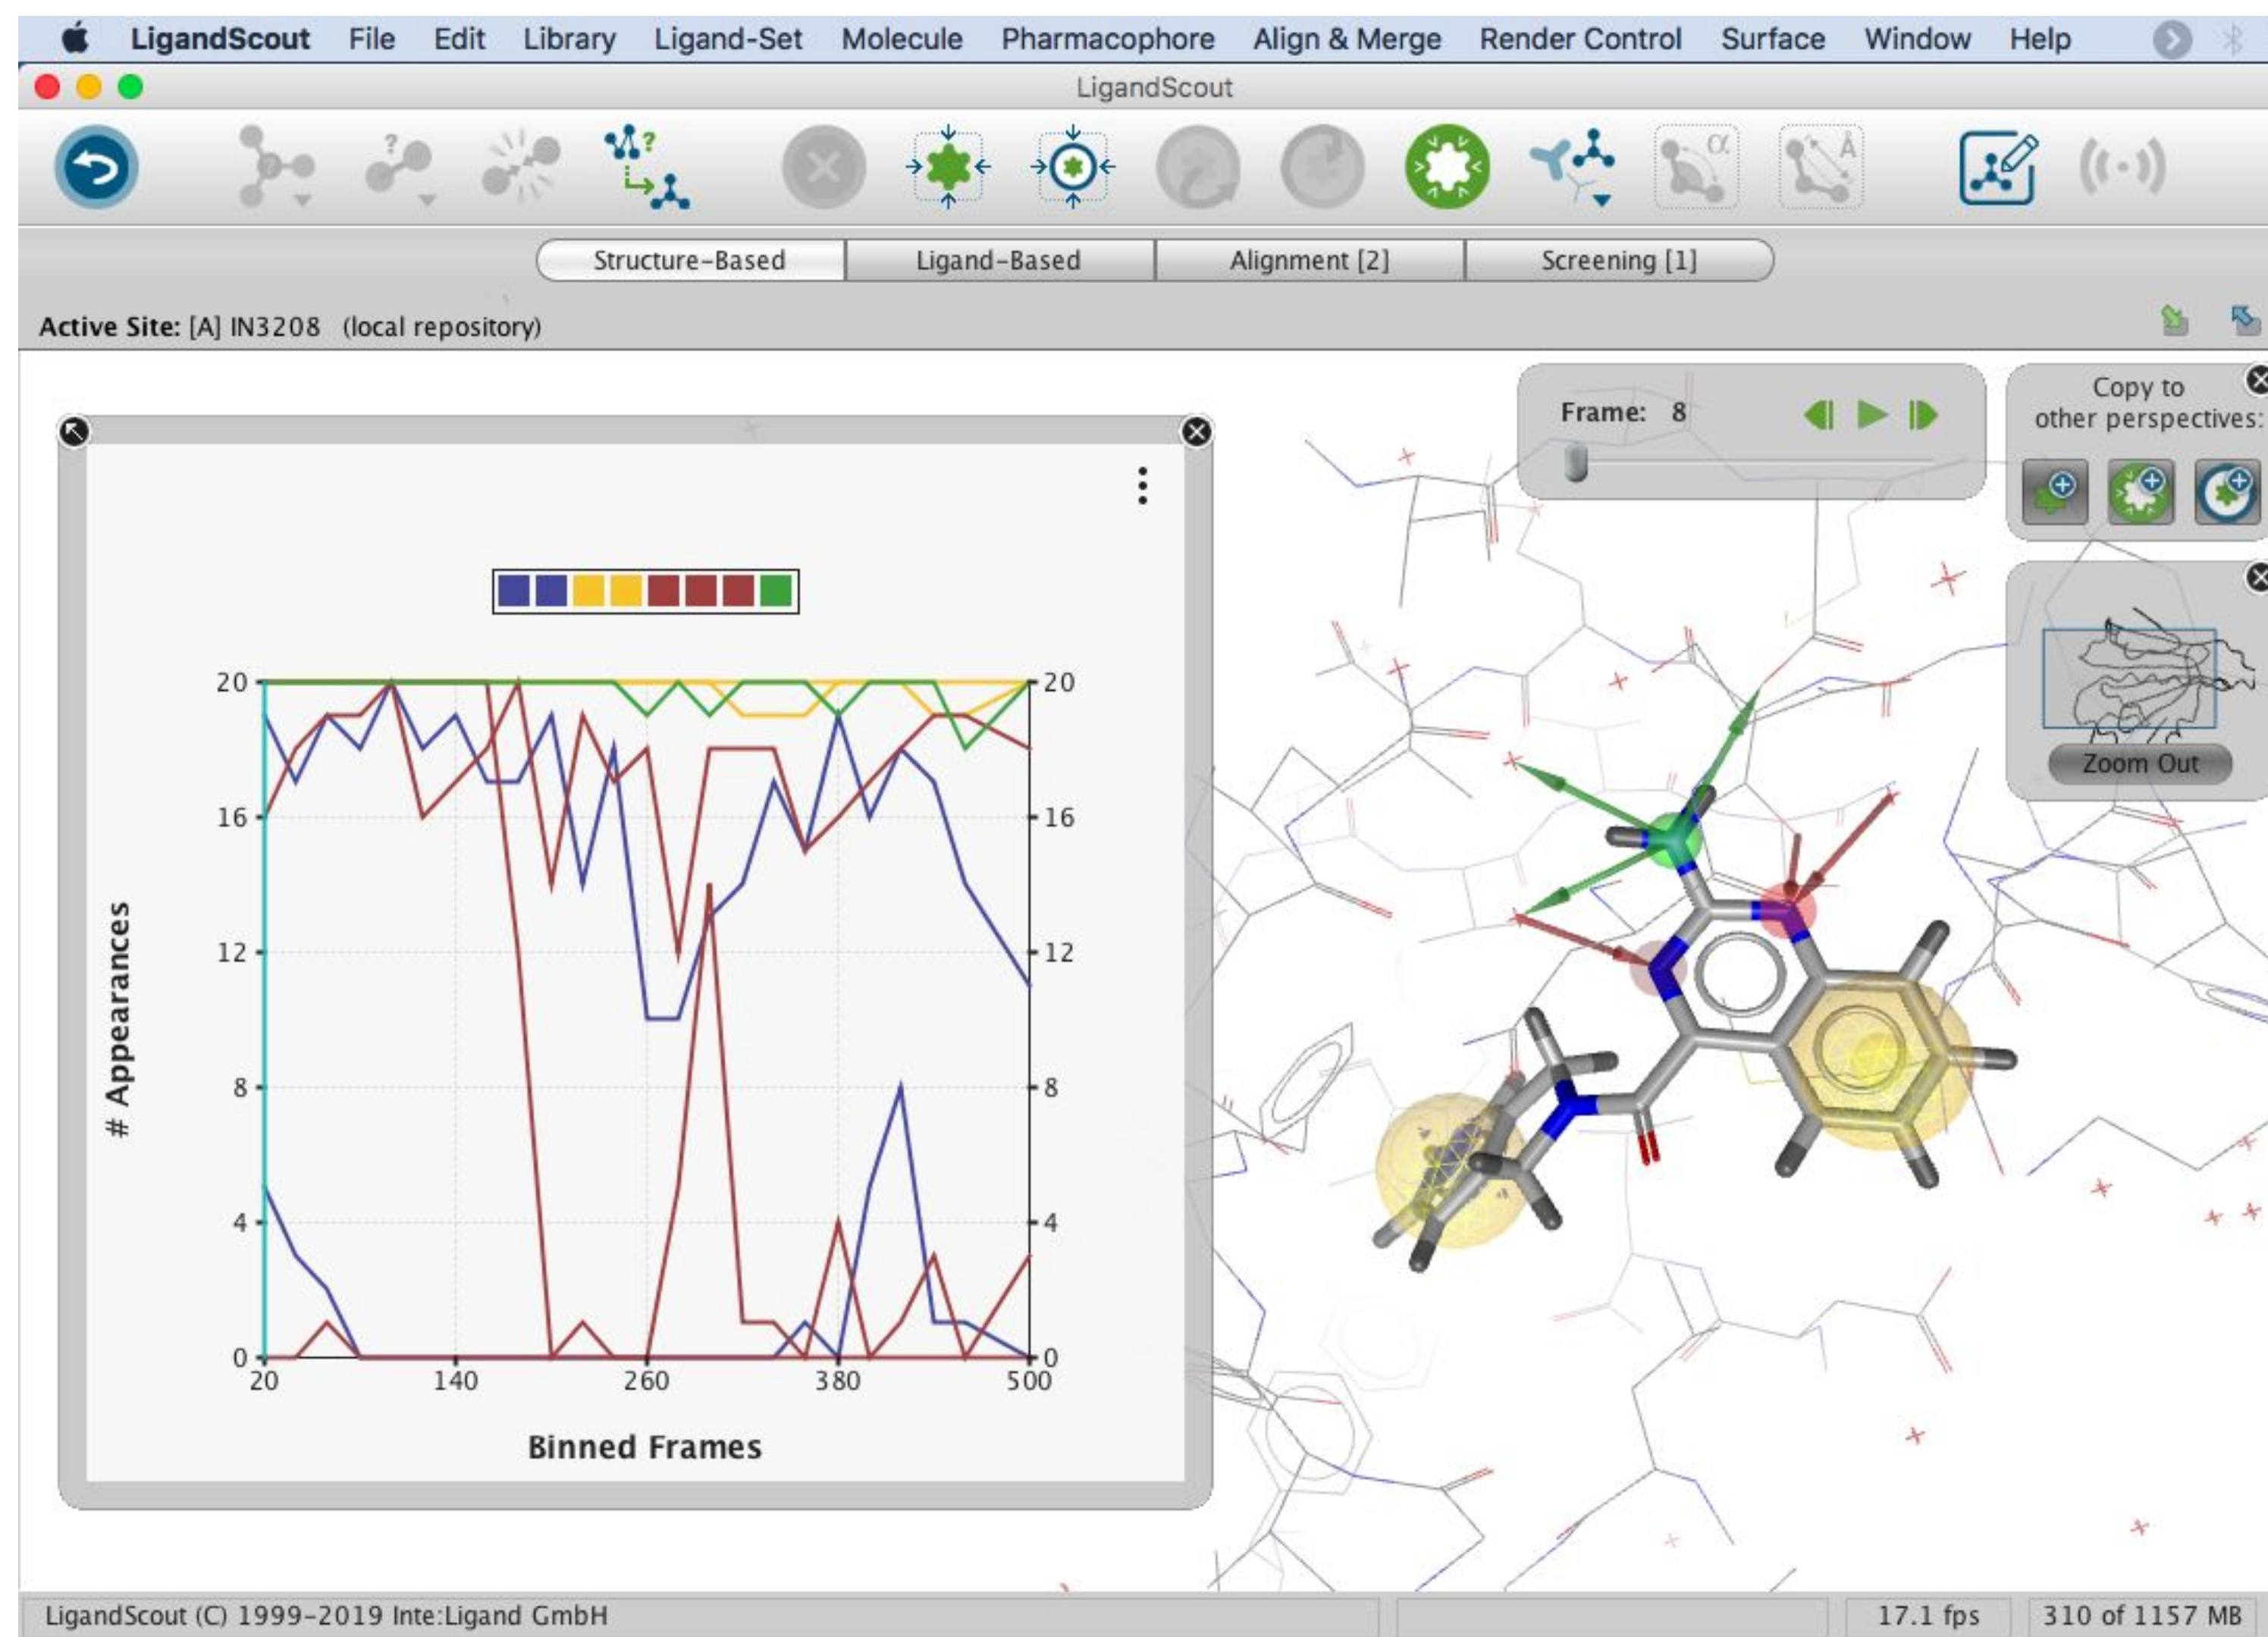

Pharmacophores: An Old Fashioned Concept ?

- Not at all ... there are a lot of new and exciting developments going on

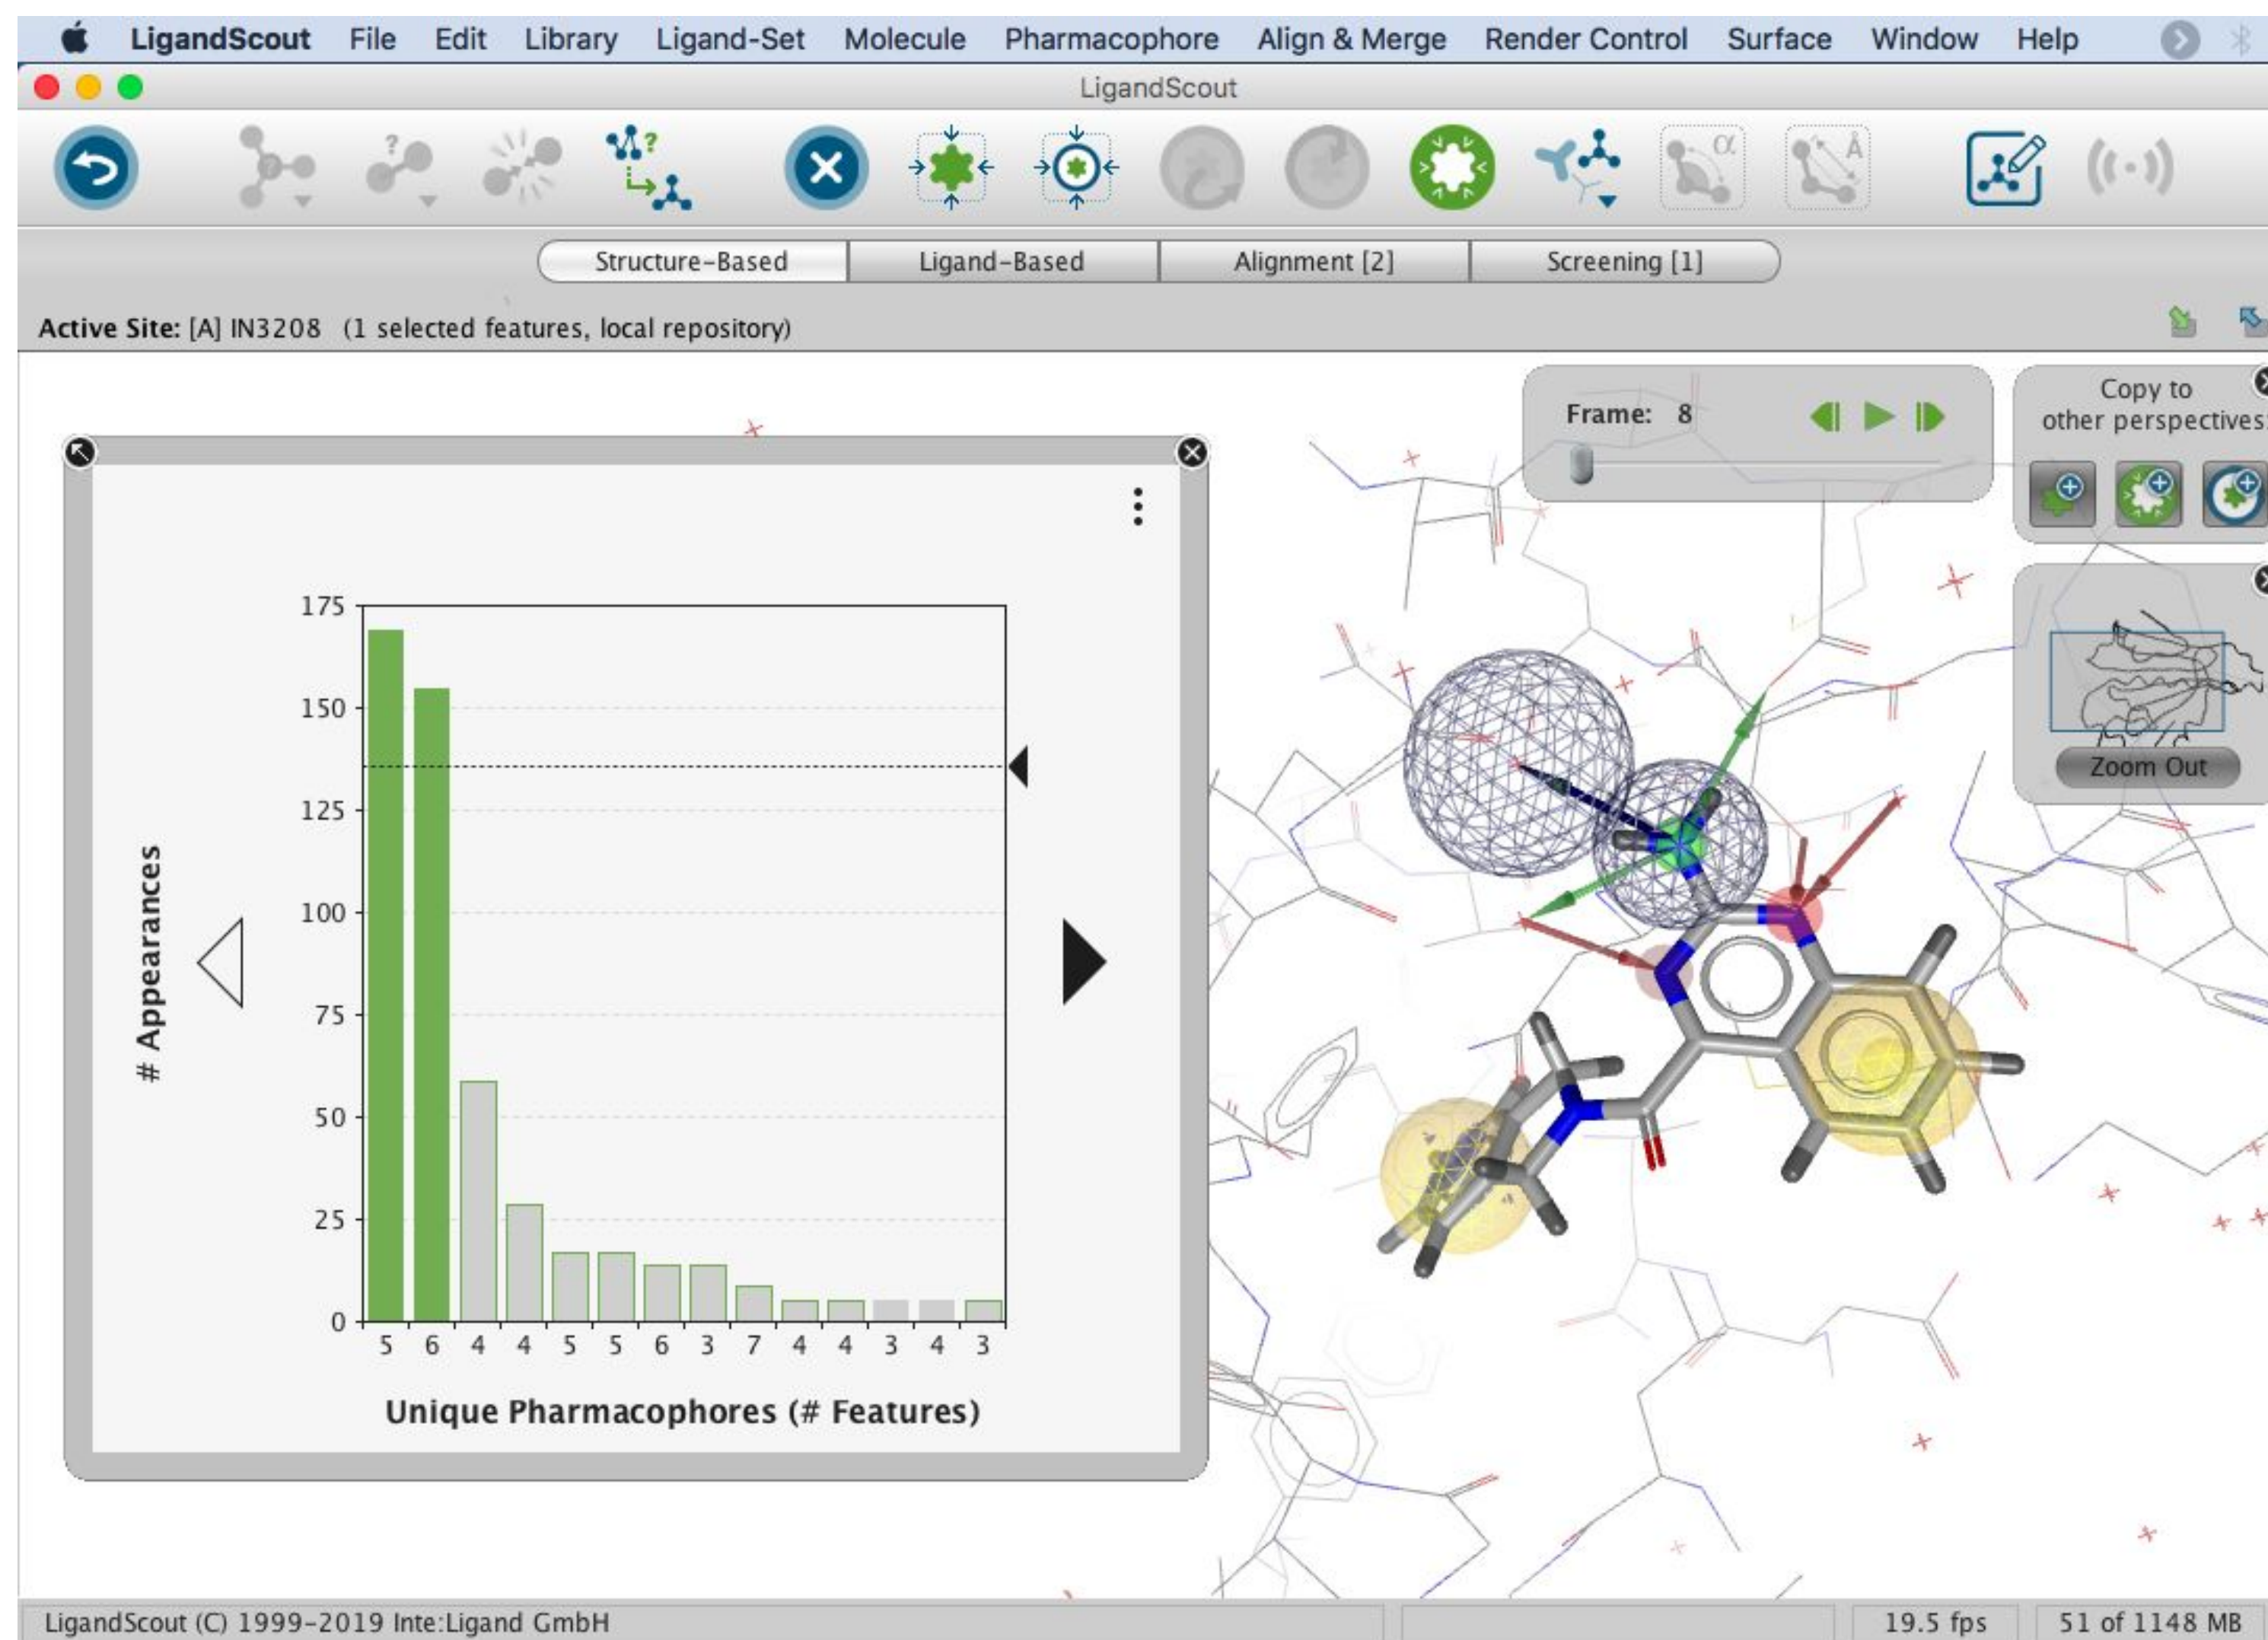

Example: MD Trajectory Analysis

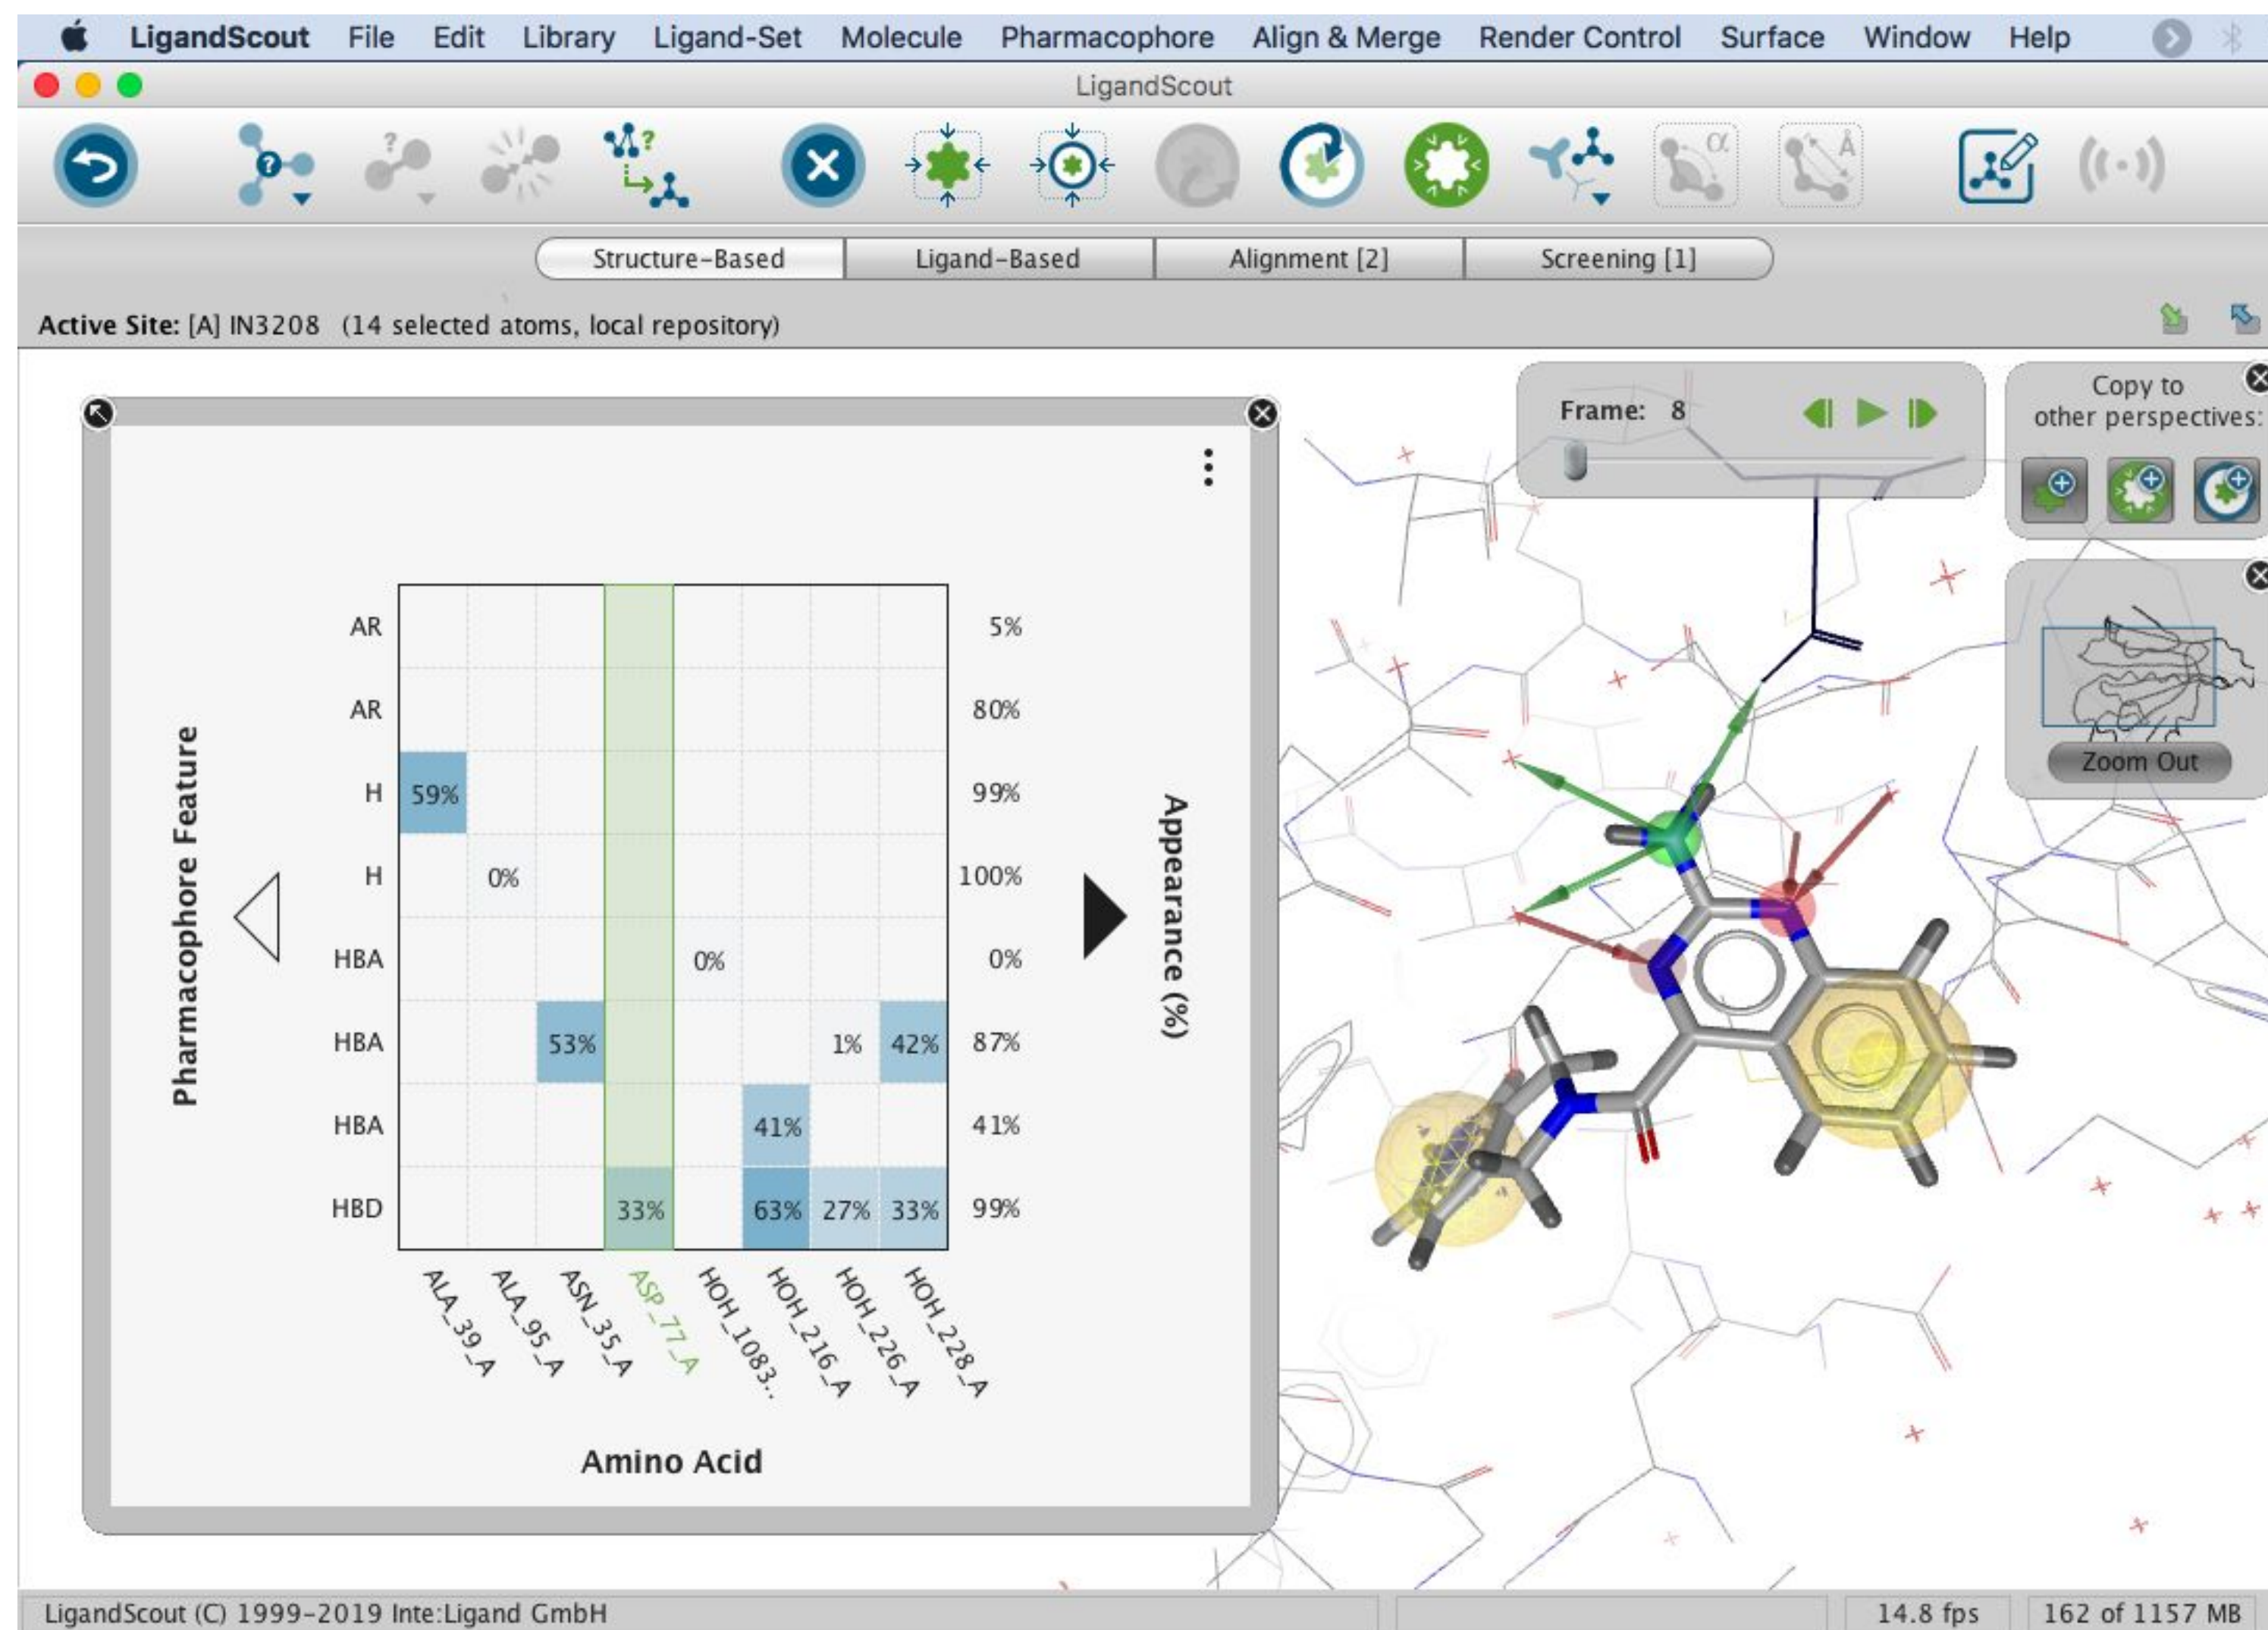

MD Feature Frequency Analysis

Find Models With Specific Features

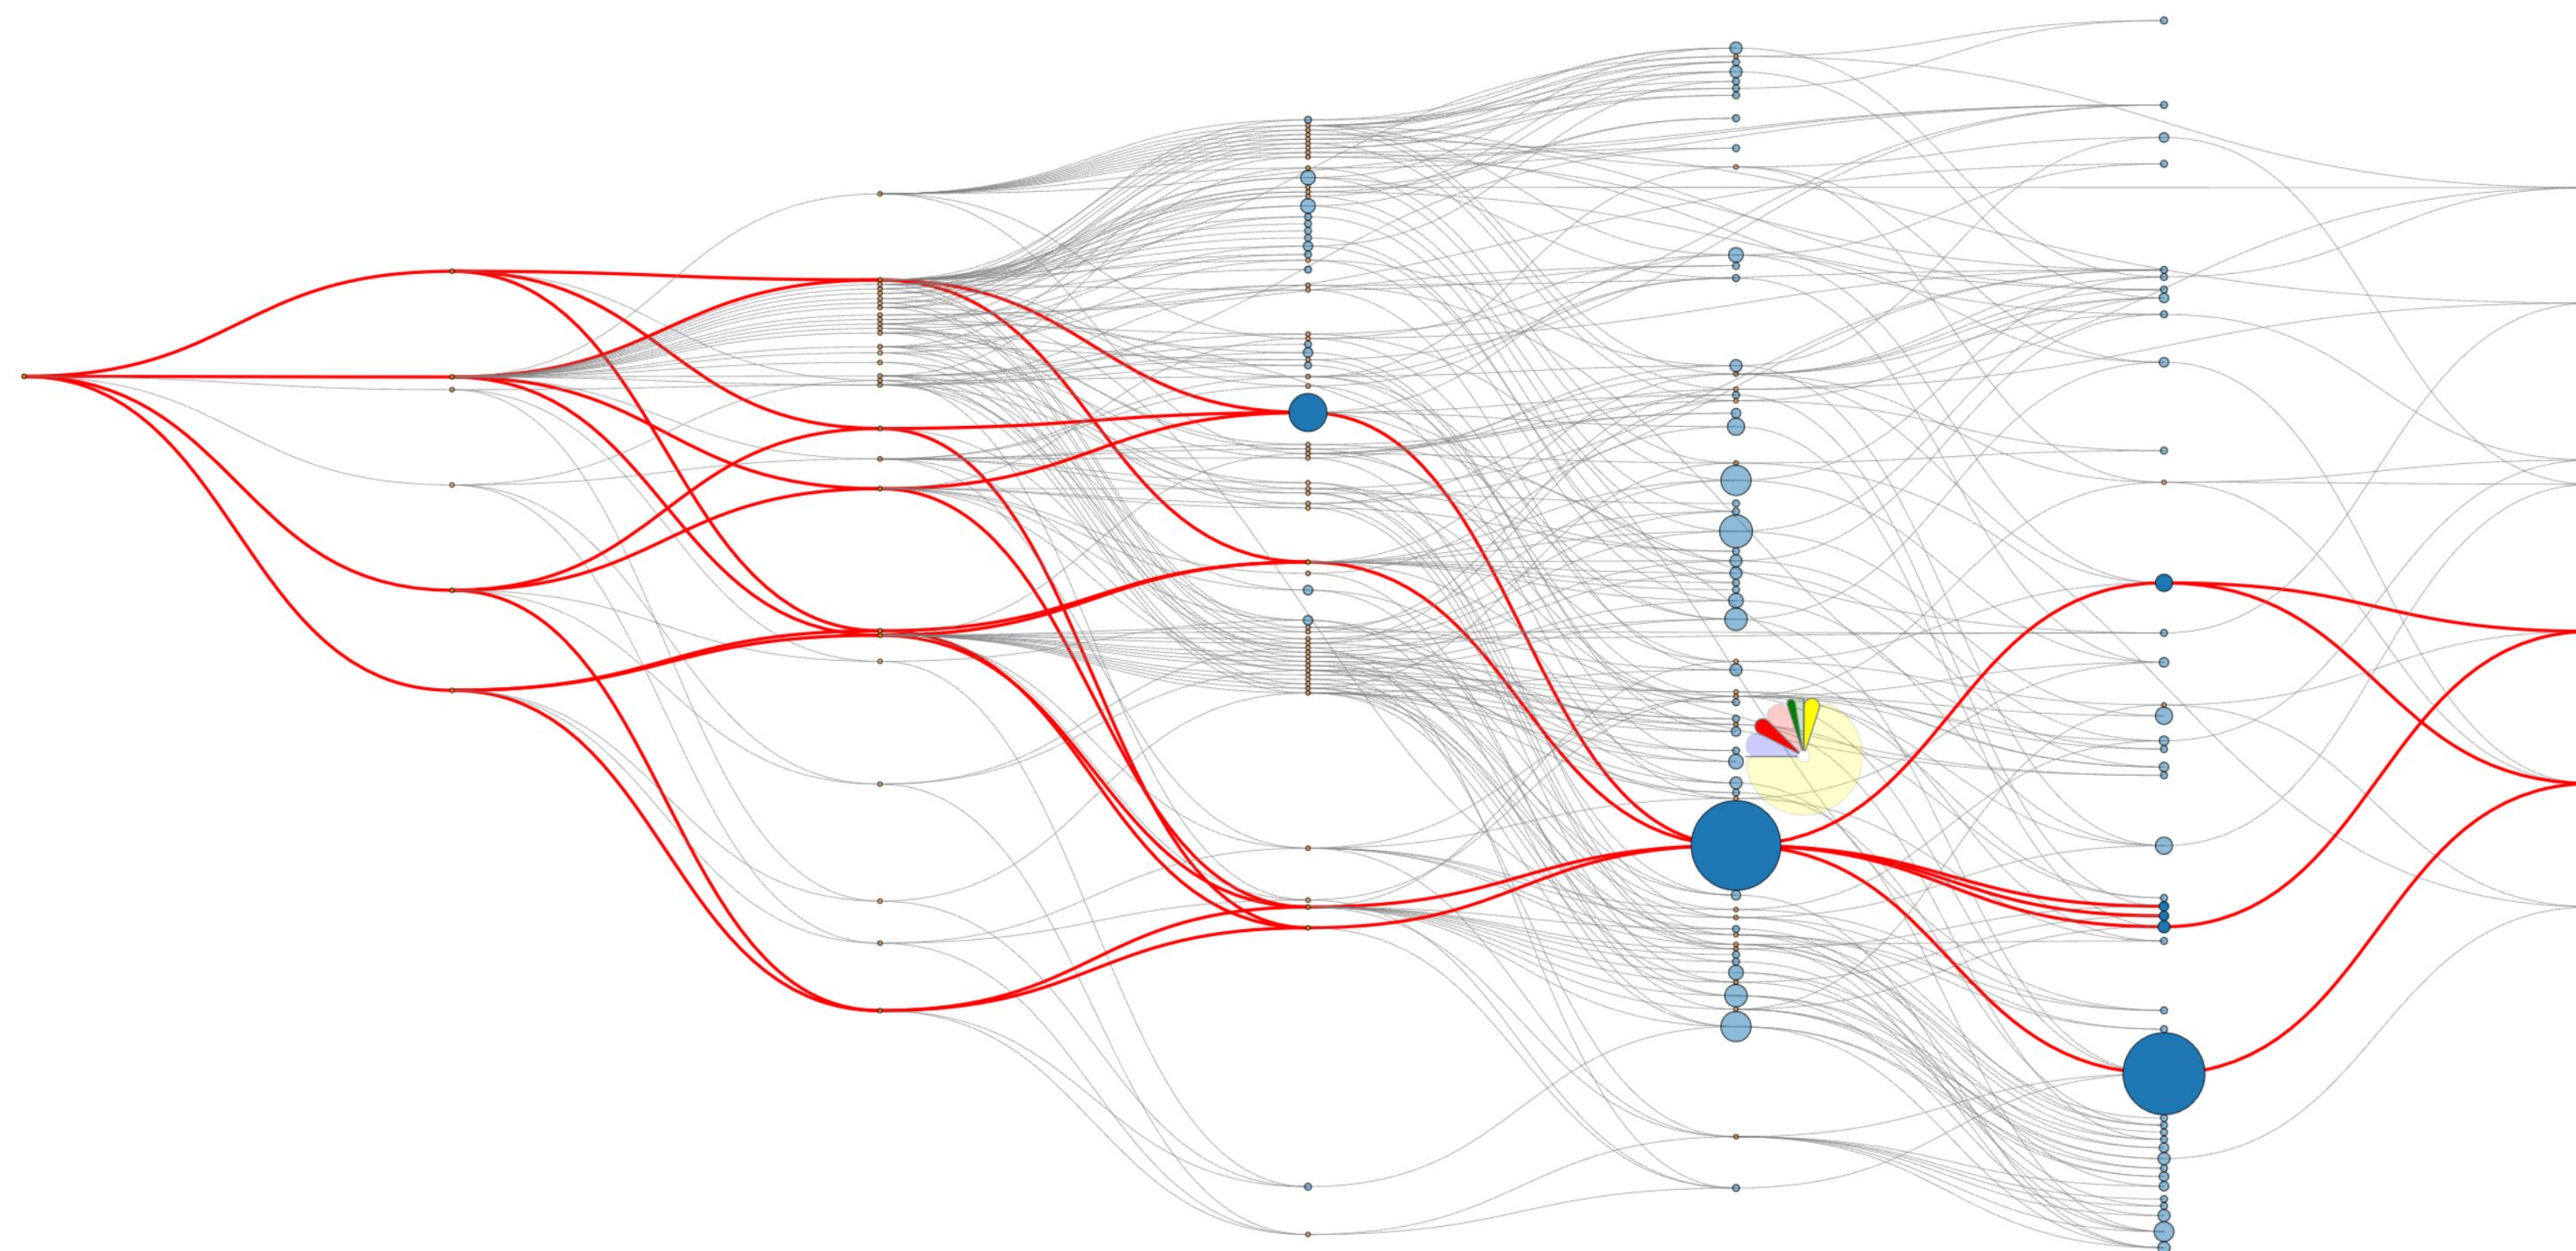

Determine Interacting Amino Acids

Hierarchical Pharmacophore Network Analysis

Selected Pharmacophores:

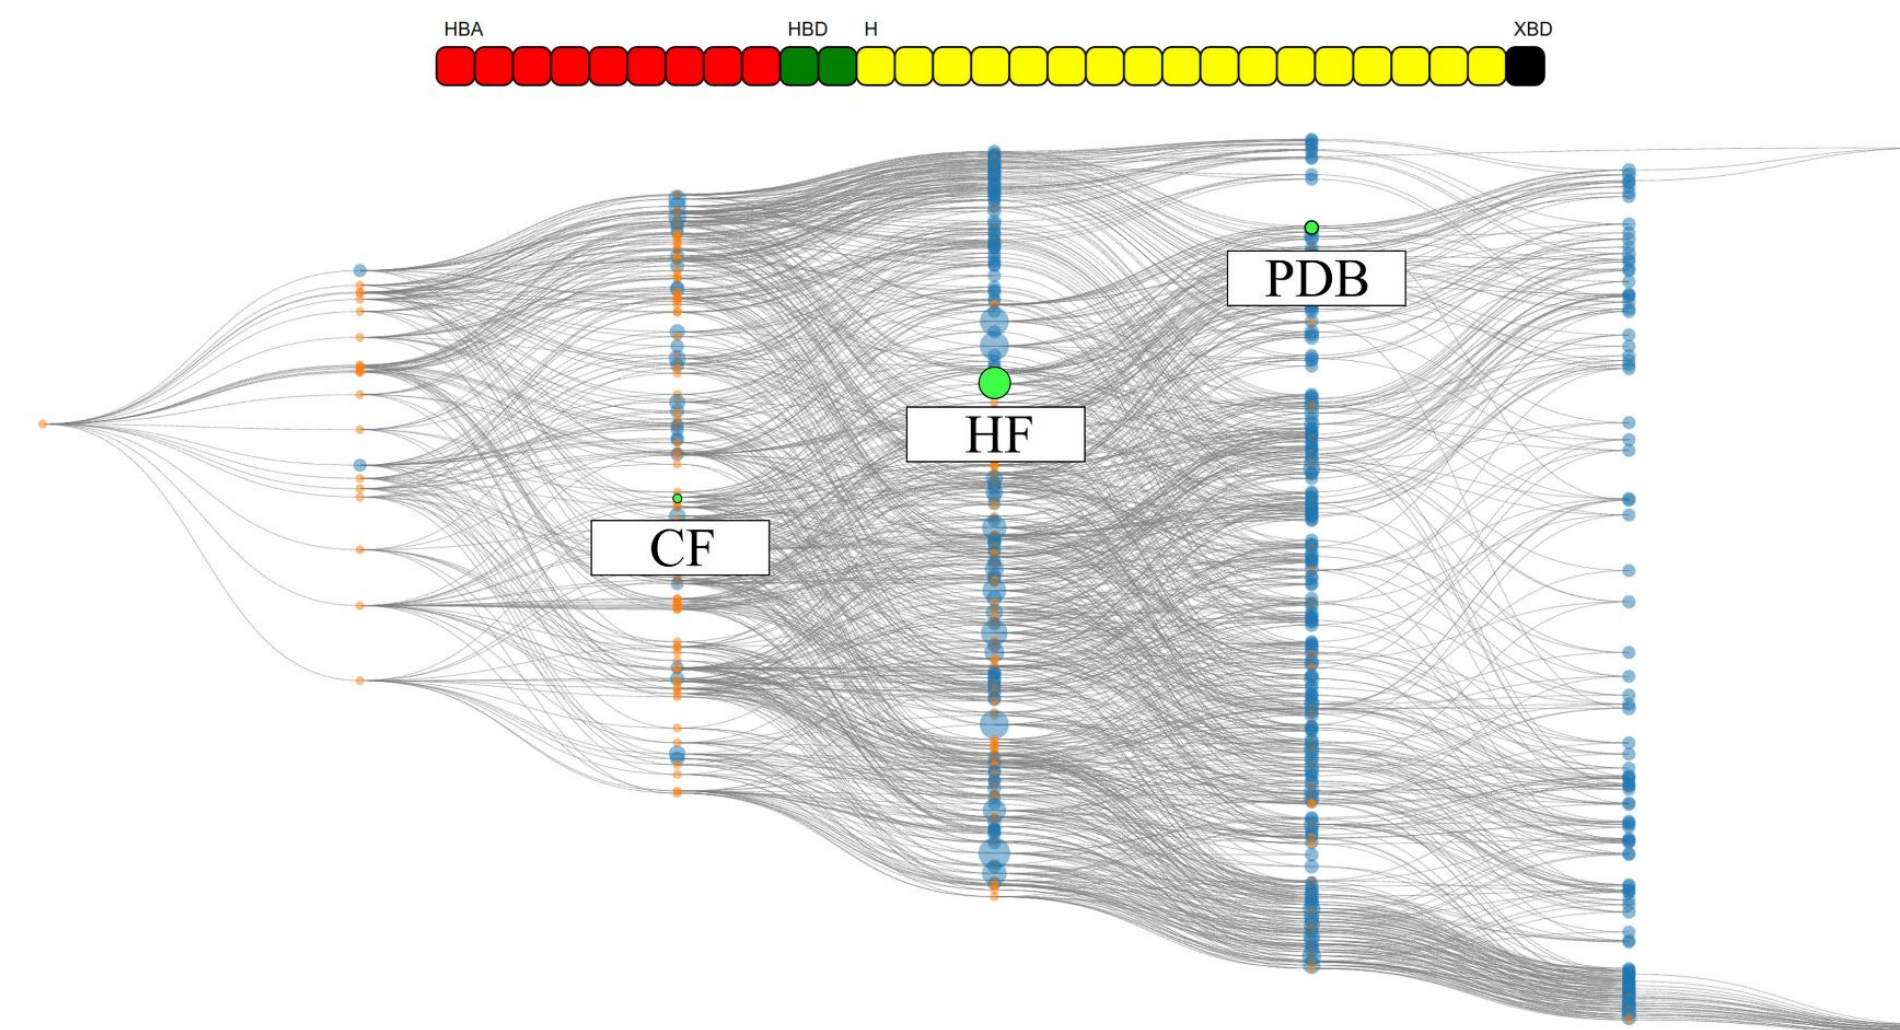

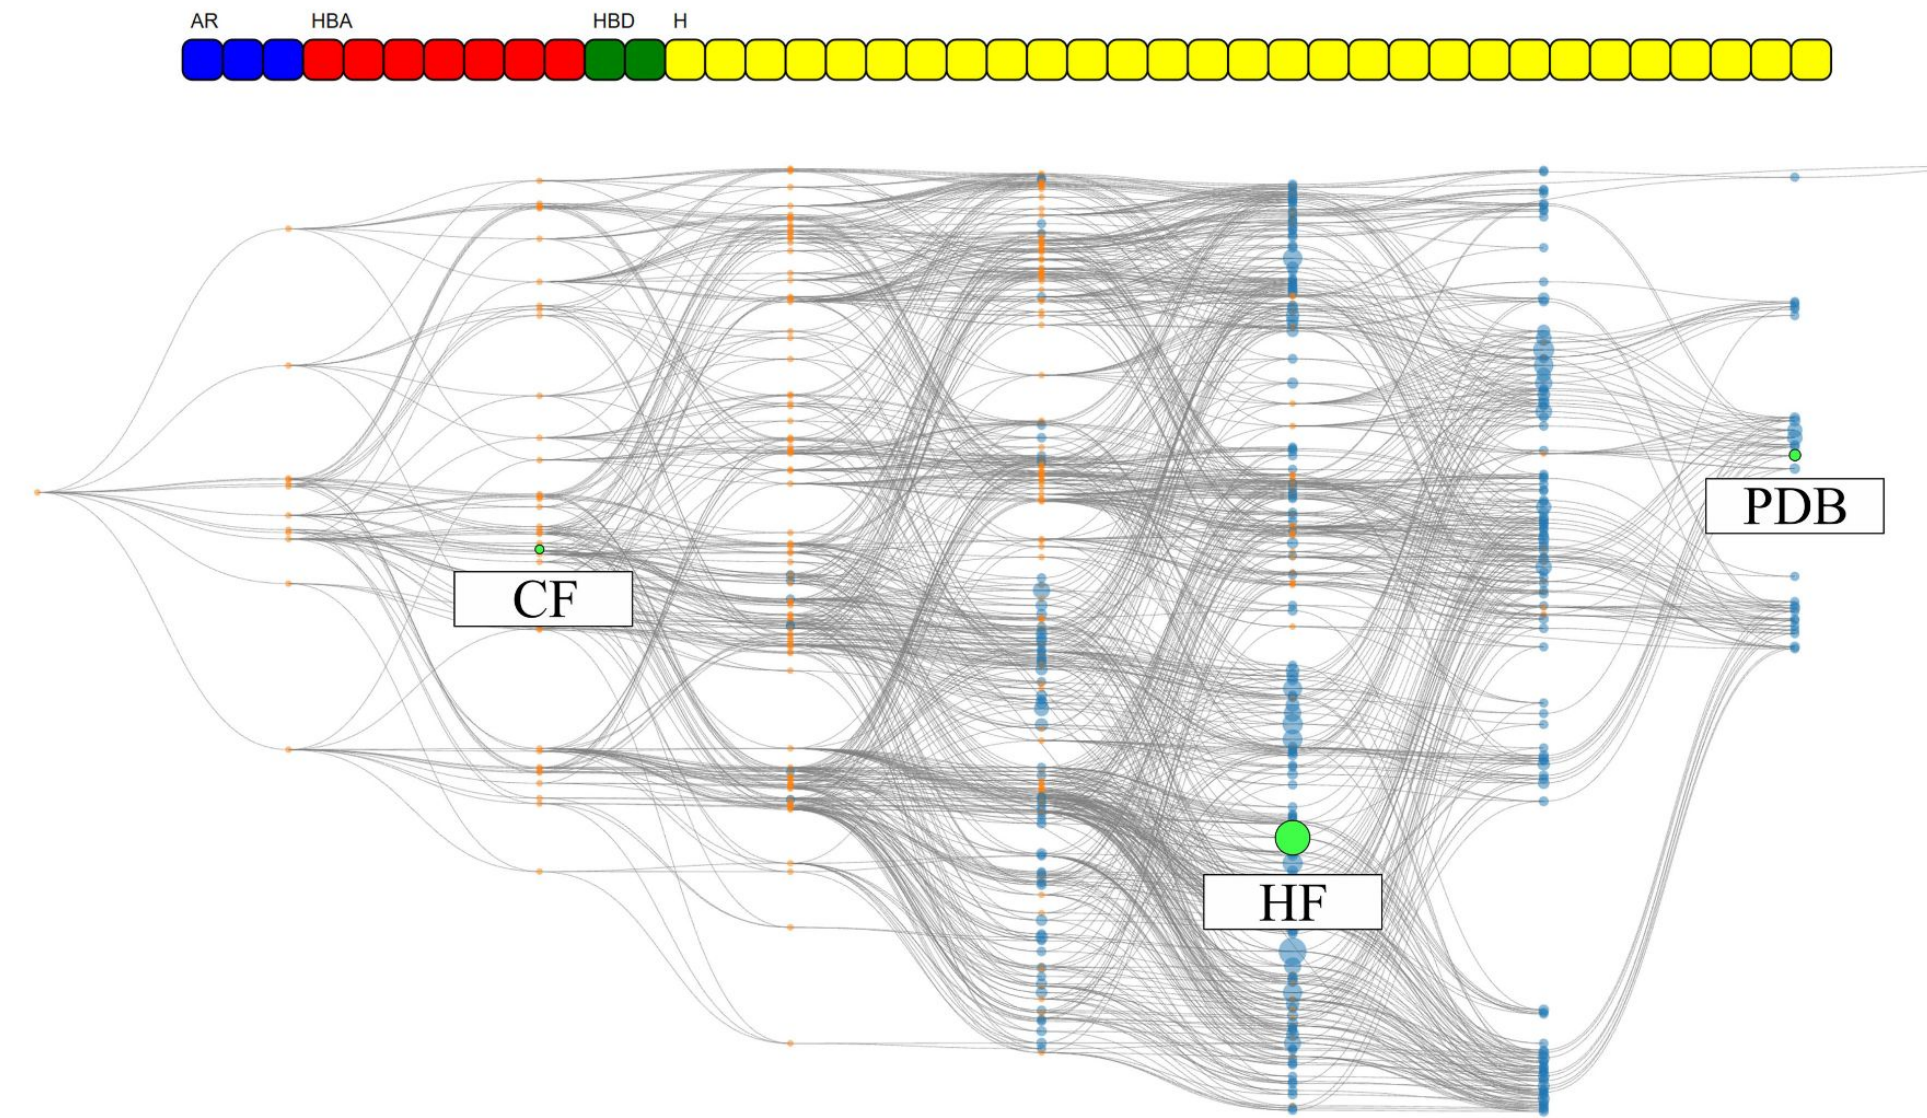

Arthur Garon

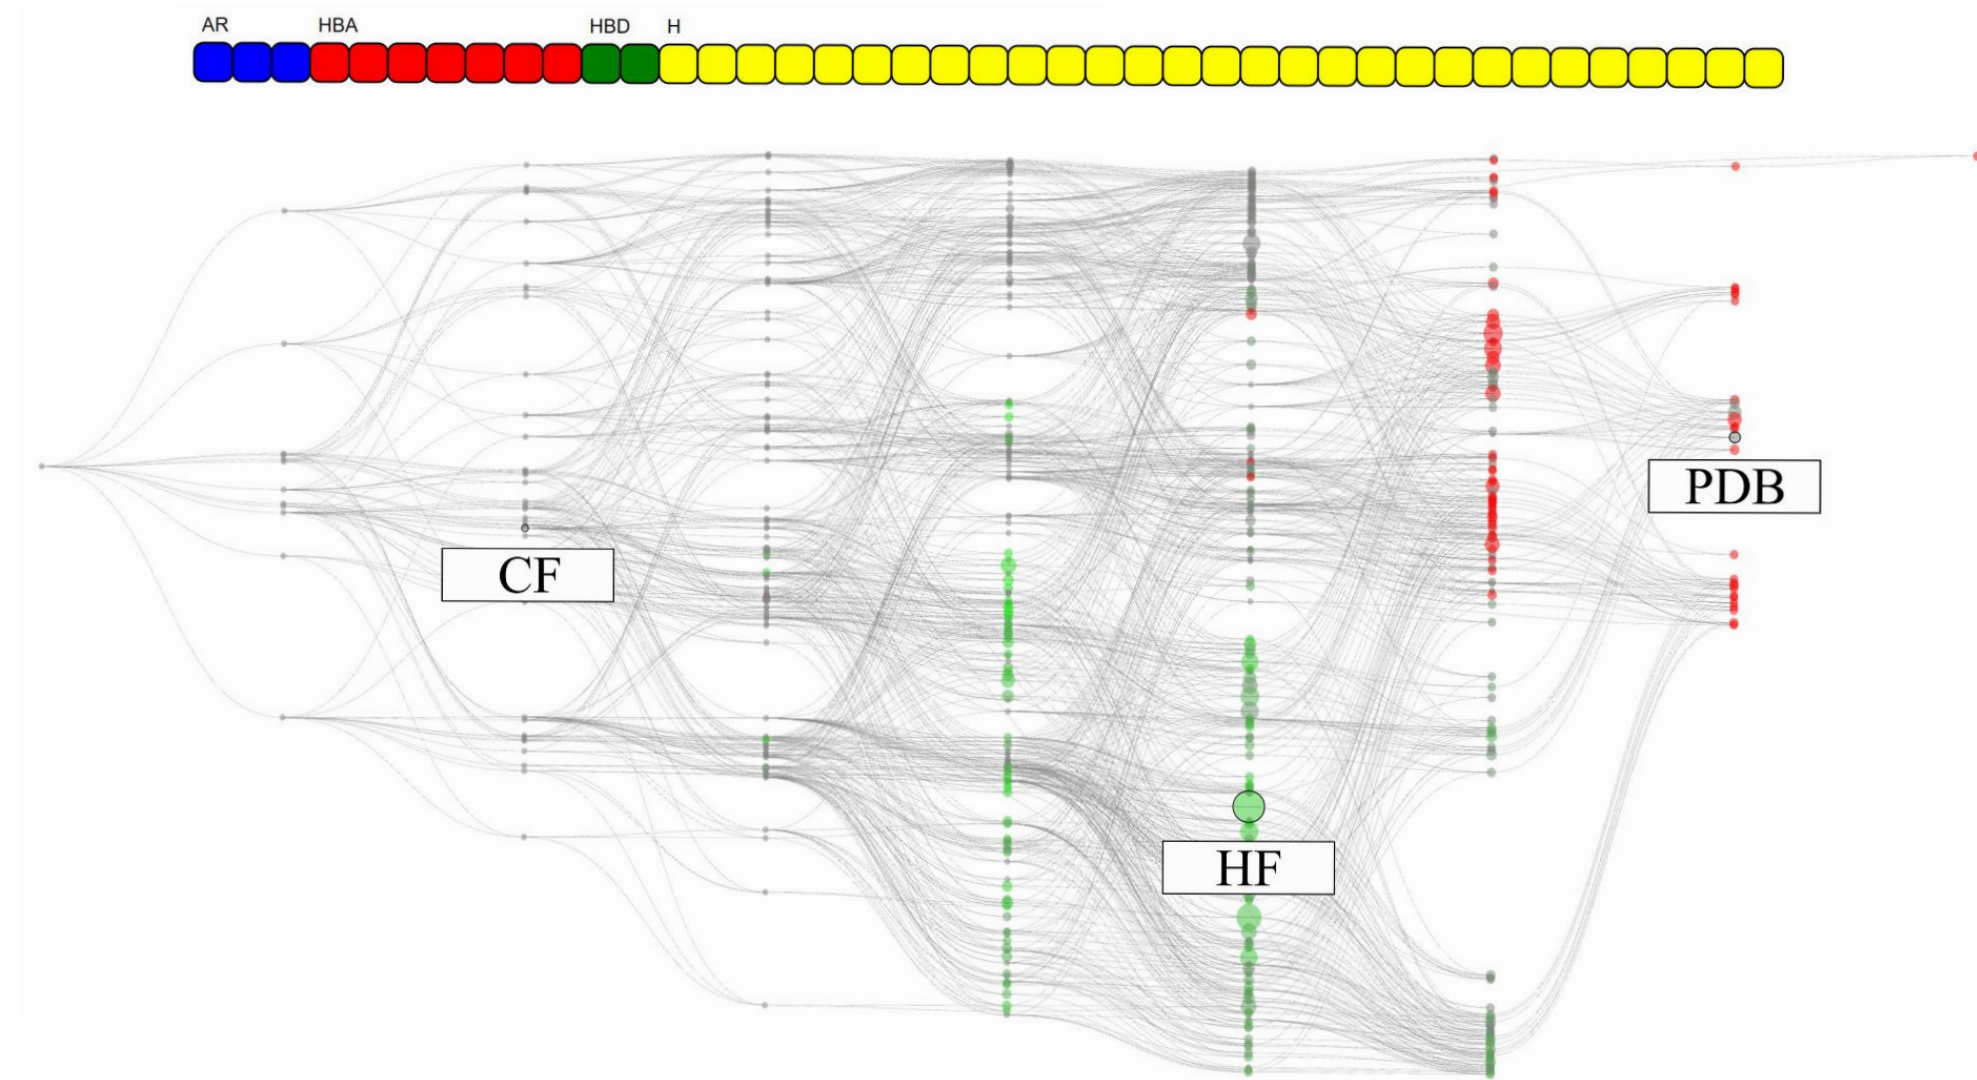

Glucokinase Case Study

- Analysis of binding modes of ligands in human glucokinase: Difference in ligand behaviour, inducing formation of active or inactive form becomes evident from hierarchical pharmacophore network analysis, provides guidance for further design

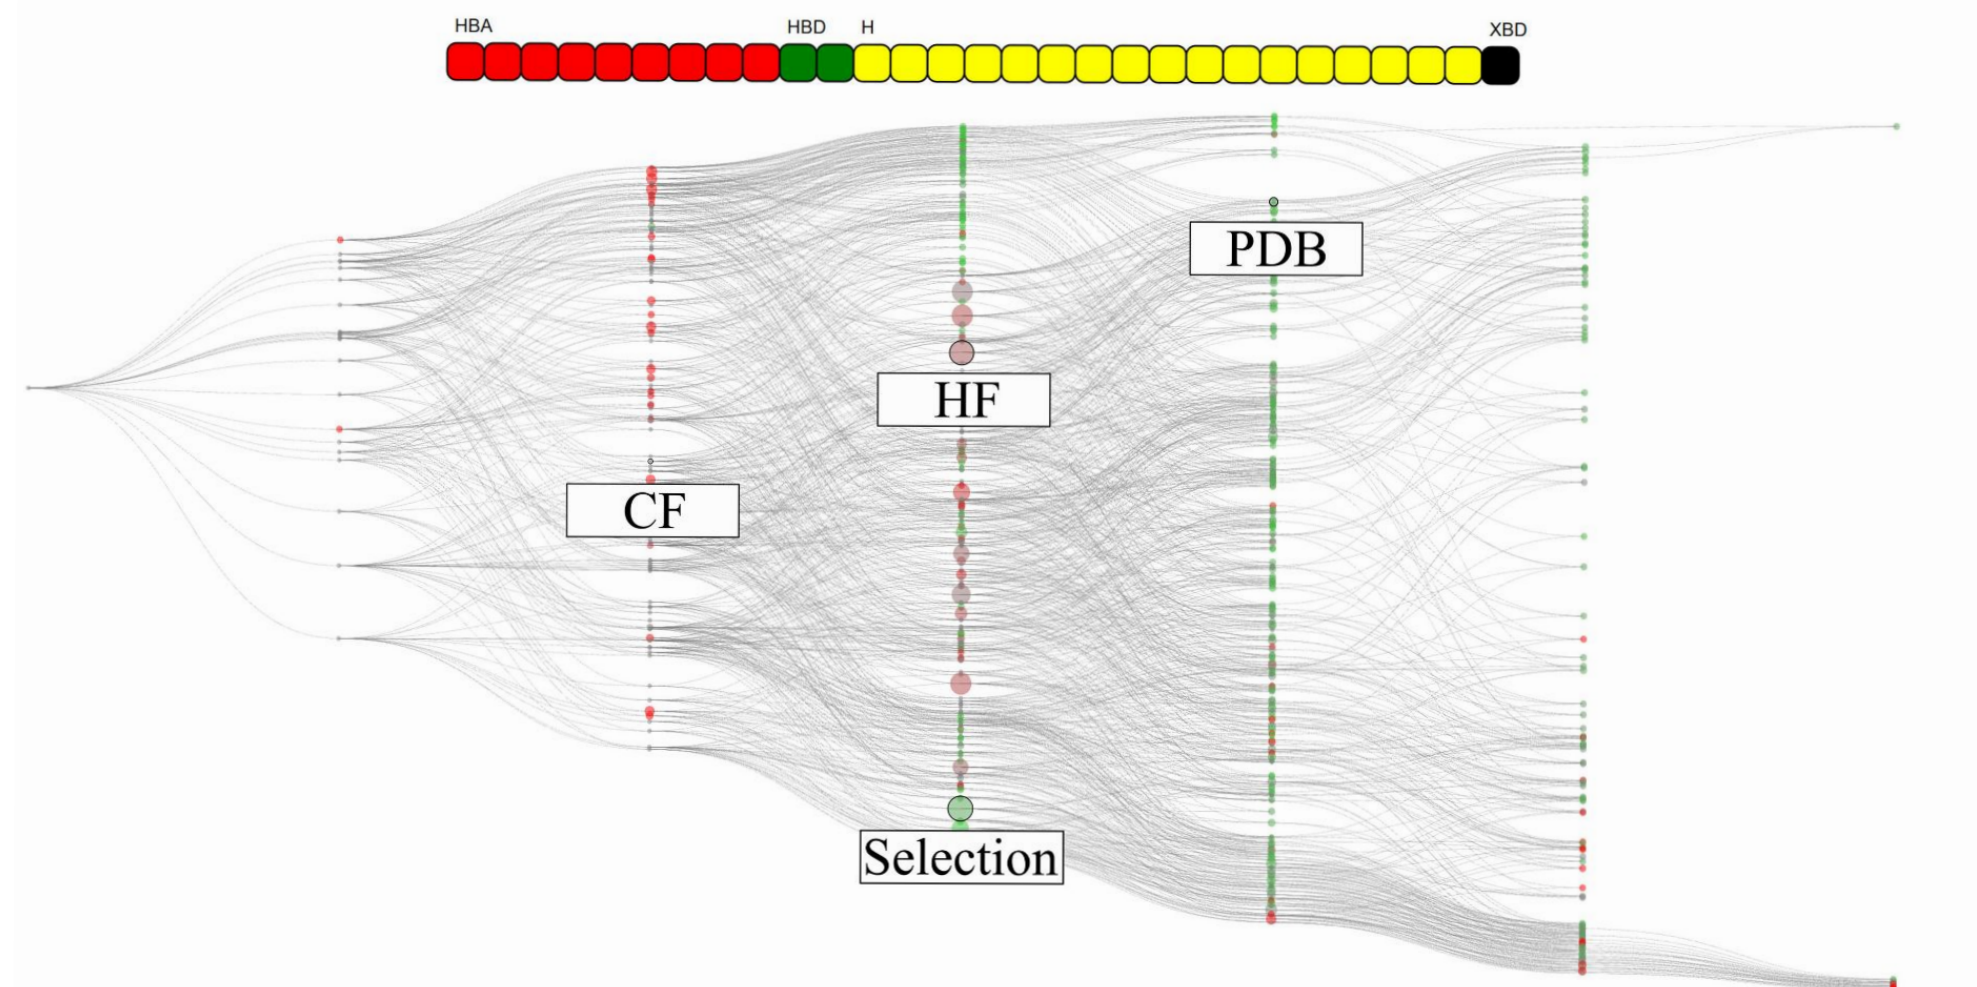

Glucokinase Case Study

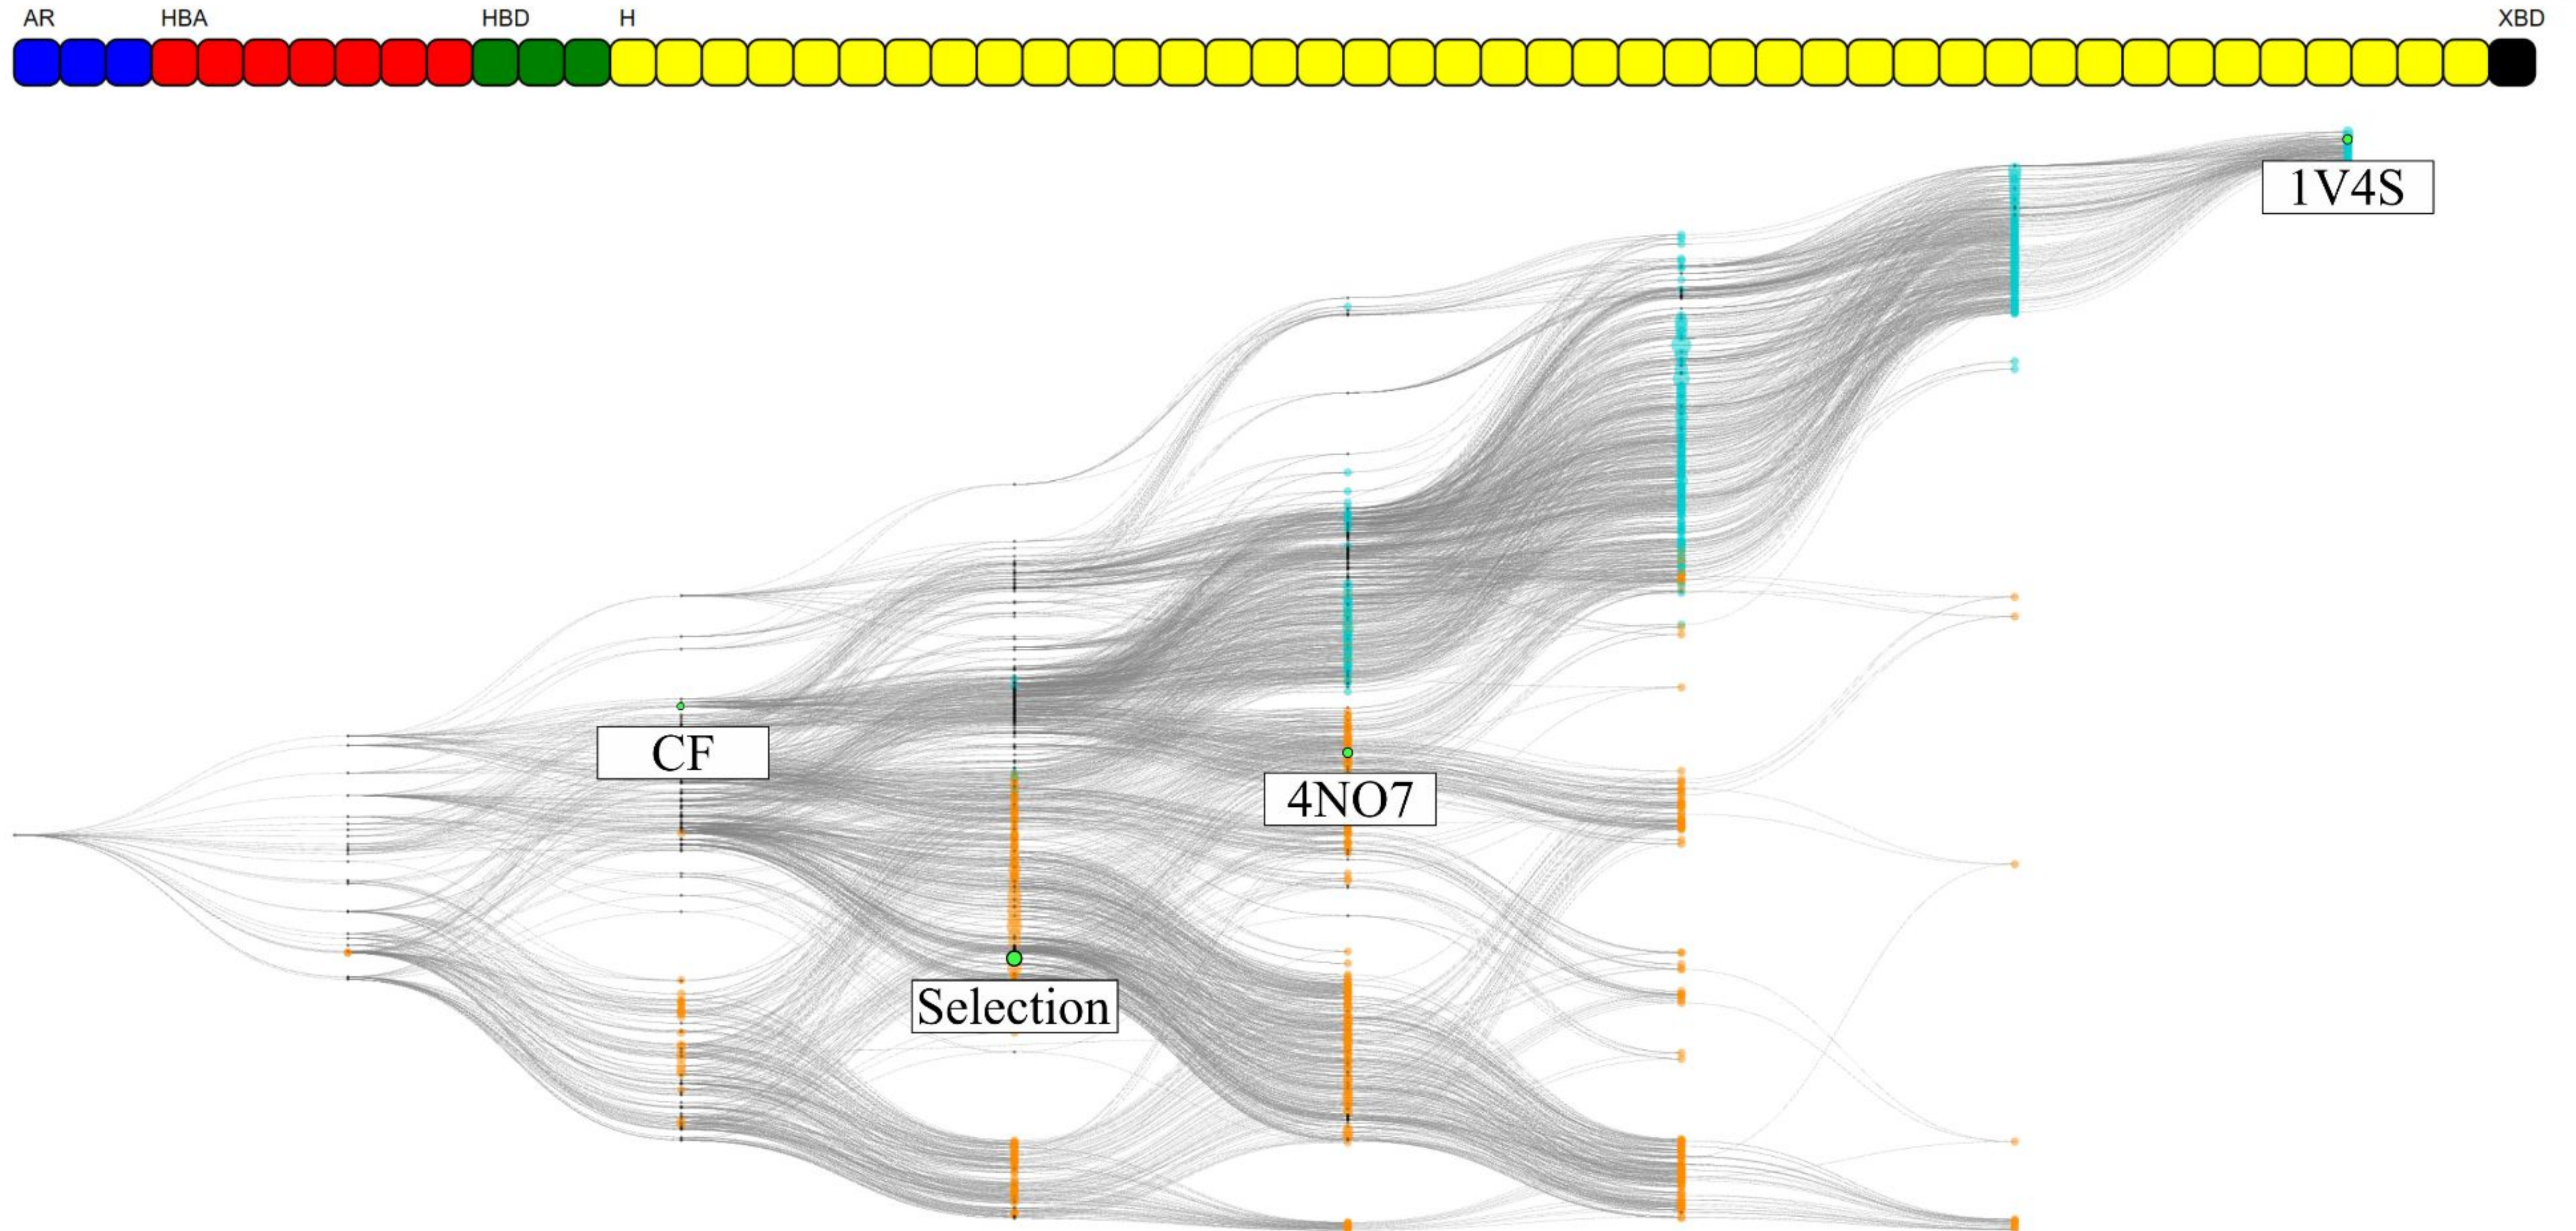

1v4s - inactive form

4no7 - active form

Glucokinase Case Study

Glucokinase Case Study

LigandScout

- Fully integrated molecular design package
- High end GUI & command line tools
- Workflow integration into KNIME
- World wide user basis
- Leading solution for pharmacophore based modelling
- Next generation capabilities in active development:
 - faster high throughput on giga-scale libraries
 - interactive pharmacophore-based clustering ...

Protein Interface Pharmacophore Mapping Tools for Small Molecule Protein: Protein Interaction Inhibitor Discovery

Arnout Voet^{1,*}, Eleanor F. Banwell², Kamlesh K. Sahu¹, Jonathan G. Heddle² and Kam Y. J. Zhang¹

¹Zhang Initiative Research Unit, and ²Heddle Initiative Research Unit, Advanced Science Institute, RIKEN, 2-1 Hiro-sawa, Wako, Saitama 351-0198, Japan

Abstract: Protein:protein interactions are becoming increasingly significant as potential drug targets; however, the rational identification of small molecule inhibitors of such interactions remains a challenge. Pharmacophore modelling is a popular tool for virtual screening of compound libraries, and has previously been successfully applied to the discovery of

ligands in the field of protein:protein interaction inhibition. In this review, we explore the interaction of pharmacophore mapping methods that have these successful cases demonstrate the usefulness depending on the available structural infor-

Pharmacophore-Based Discovery of Small-Molecule Inhibitors of Protein-Protein Interactions between HIV-1 Integrase and Cellular Cofactor LEDGF/p75

Laura De Luca,^{*(a)} Maria Letizia Barreca,^{*(b)} Stefania Ferro,^(a) Frauke Christ,^(c) Nunzio Iraci,^(b) Rosaria Gitto,^(a) Anna Maria Monforte,^(a) Zeger Debyser,^{*(c)} and Alba Chimirri^(a)

The cellular protein lens epithelium transcriptional coactivator p75 (LED) in HIV integration. The protein-protein interaction between HIV-1 integrase (IN) and its cofactor LEDGF/p75 may therefore serve as targets for anti-HIV drugs. In this work, a structural model for potential small-molecule inhibitors of the HIV-1 integrase-LEDGF/p75 interaction was developed using a combination of computational and experimental approaches. The 3D model obtained was used for the identification of our in-house chemical database. The identification of compound CHIBA-101 was followed by further optimization. The rationale

New Use for an Old Drug: Inhibiting ABCG2 with Sorafenib

Yinxiang Wei^{1,3}, Yuanfang Ma³, Qing Zhao^{1,4}, Zhiguang Ren^{1,3}, Yan Li¹, Tingjun Hou², and Hui Peng¹

Abstract

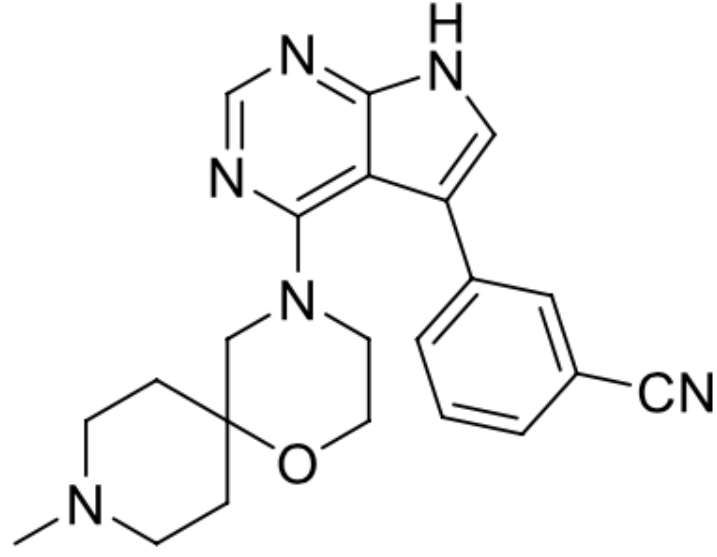

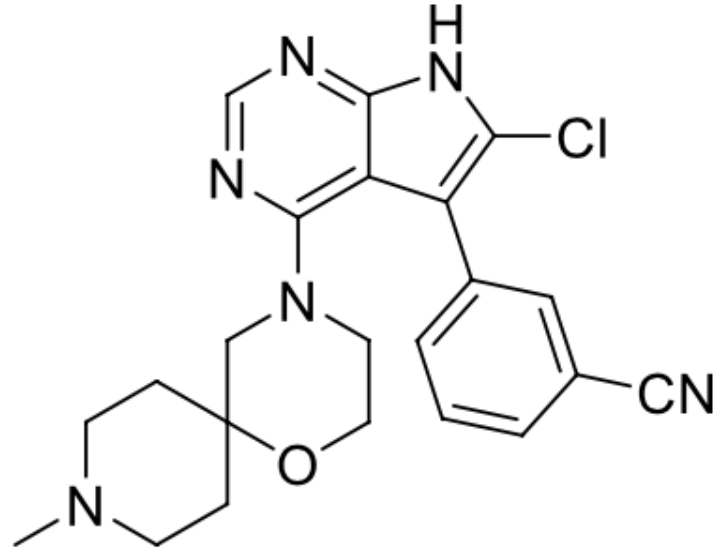

Human ABCG2, a member of the ATP-binding cassette transporter superfamily, represents a promising target for sensitizing MDR in cancer chemotherapy. Although lots of ABCG2 inhibitors were identified, none of them has been tested clinically, maybe because of several problems such as toxicity or safety and pharmacokinetic uncertainty of compounds with novel chemical structures. One efficient solution is to rediscover new uses for existing drugs with known pharmacokinetics and safety profiles. Here, we found the new use for

Supporting Information

ABSTRACT: Knowledge of the putative bound-state conformation of a molecule is an essential prerequisite for the successful application of many computer-aided drug design methods that aim to assess or predict its capability to bind to a particular target receptor. An established approach to predict bioactive conformers in the absence of receptor structure information is to sample the low-energy conformational space of the investigated molecules and derive representative conformer ensembles that can be expected to comprise members closely resembling possible bound-state ligand conformations. The high relevance of such conformer generation functionality led to the development of a wide panel of dedicated commercial and open-source software tools throughout the last decades. Several published benchmarking studies have shown that open-source tools usually lag behind their commercial competitors in many key aspects. In this work, we introduce the open-source conformer ensemble generator CONFORGE, which aims at delivering state-of-the-art performance for all types of organic molecules in drug-like chemical space. The ability of CONFORGE and several well-known commercial and open-source conformer ensemble generators to reproduce experimental 3D structures as well as their computational efficiency and robustness has been assessed thoroughly for both typical drug-like molecules and macrocyclic structures. For small molecules, CONFORGE clearly outperformed all other tested open-source conformer generators and performed at least equally well as the evaluated commercial generators in terms of both processing speed and accuracy. In the case of macrocyclic structures, CONFORGE achieved the best average accuracy among all benchmarked generators, with RDKit's generator coming close in second place.

- Novel conformer generator based on LigandScout iCon
- Available in CDPKit
- Improved small compound performance accuracy
 - Especially for complex compounds such as macrocycles
- Integration into LigandScout XT
 - Faster database generation & possibly better screening hits

* Correspondence: thomas.seidel@univie.ac.at

Abstract: Chemical features of small molecules can be abstracted to 3D pharmacophore models, which are easy to generate, interpret, and adapt by medicinal chemists. Three-dimensional pharmacophores can be used to efficiently match and align molecules according to their chemical feature pattern, which facilitates the virtual screening of even large compound databases. Existing alignment methods, used in computational drug discovery and bio-activity prediction, are often not suitable for finding matches between pharmacophores accurately as they purely aim to minimize RMSD or maximize volume overlap, when the actual goal is to match as many features as possible within the positional tolerances of the pharmacophore features. As a consequence, the obtained alignment results are often suboptimal in terms of the number of geometrically matched feature pairs, which increases the false-negative rate, thus negatively affecting the outcome of virtual screening experiments. We addressed this issue by introducing a new alignment algorithm, Greedy 3-Point Search (G3PS), which aims at finding optimal alignments by using a matching-feature-pair maximizing search strategy while at the same time being faster than competing methods.

Keywords: pharmacophore alignment; pharmacophore modelling; virtual screening; greedy algorithm; drug design

1. Introduction

Christian Permann

G3PS Alignment

- How can we improve on previous method ?

(a) Two pharmacophores

(b) RMSD or
volume-based alignment

(c) Desired alignment

G3PS Alignment

- Another common pitfalls
 - Failing on exclusion volume spheres
 - Barely touching exclusion volume invalidates alignment
 - Allowing omission of m out of f features
 - for each value $r = \{0..m\}$
 - 1. Create all combinations with $(f - r)$ features
 - 2. Perform alignment for each combination
 - #Alignments = $P_m f = O(f^m) \rightarrow$ exponential in m

$$\sum_{r=0}^m \binom{f}{r} = O(f^m) \rightarrow$$

- New algorithm is based on iterative improvement of heuristic guesses
- Runtime
 - Much faster than previous methods
 - Independent of number of potentially omitted features
 - User-defined number of computed guesses: Runtime vs Accuracy tuneable
- Found Alignments
 - More accurate retrieval according to user query
 - Optimised for maximum number of matched features
 - Adapts also to exclusion volume spheres

Heuristic Alignment Trees

- Steers alignment between faster runtimes & more accurate retrieval
- Represents the number of (three-point) starting configurations
- Higher number will better sample solution space
 - more correctly identified hits
- Smaller number will result in a faster screening
- Runtime increases less than linearly with number of tries
 - e.g. changing from 20 to 50 - results in approximately 25% longer runtime
- Recommended settings
 - 50 for generic fast run, 300 for generic accurate run

Some More Examples

- New graph neural network architecture for better prediction of standard molecular properties (logP, logS, logD)
- New protein-ligand descriptors for machine learning
- Novel representation of pharmacophore models for machine learning
- Extending pharmacophore based virtual screening for exa-scale libraries

Abstract: The accurate prediction of molecular properties, such as lipophilicity and aqueous solubility, are of great importance and pose challenges in several stages of the drug discovery pipeline. Machine learning methods, such as graph-based neural networks (GNNs), have shown exceptionally good performance in predicting these properties. In this work, we introduce a novel GNN architecture, called directed edge graph isomorphism network (D-GIN). It is composed of two distinct sub-architectures (D-MPNN, GIN) and achieves an improvement in accuracy over its sub-architectures employing various learning, and featurization strategies. We argue that combining models with different key aspects help make graph neural networks deeper and simultaneously increase their predictive power. Furthermore, we address current limitations in assessment of deep-learning models, namely, comparison of single training run performance metrics, and offer a more robust solution.

QPHAR: quantitative pharmacophore activity relationship: method and validation

Stefan Kohlbacher

Stefan M. Kohlbacher, Thierry Langer and Thomas Seidel* 

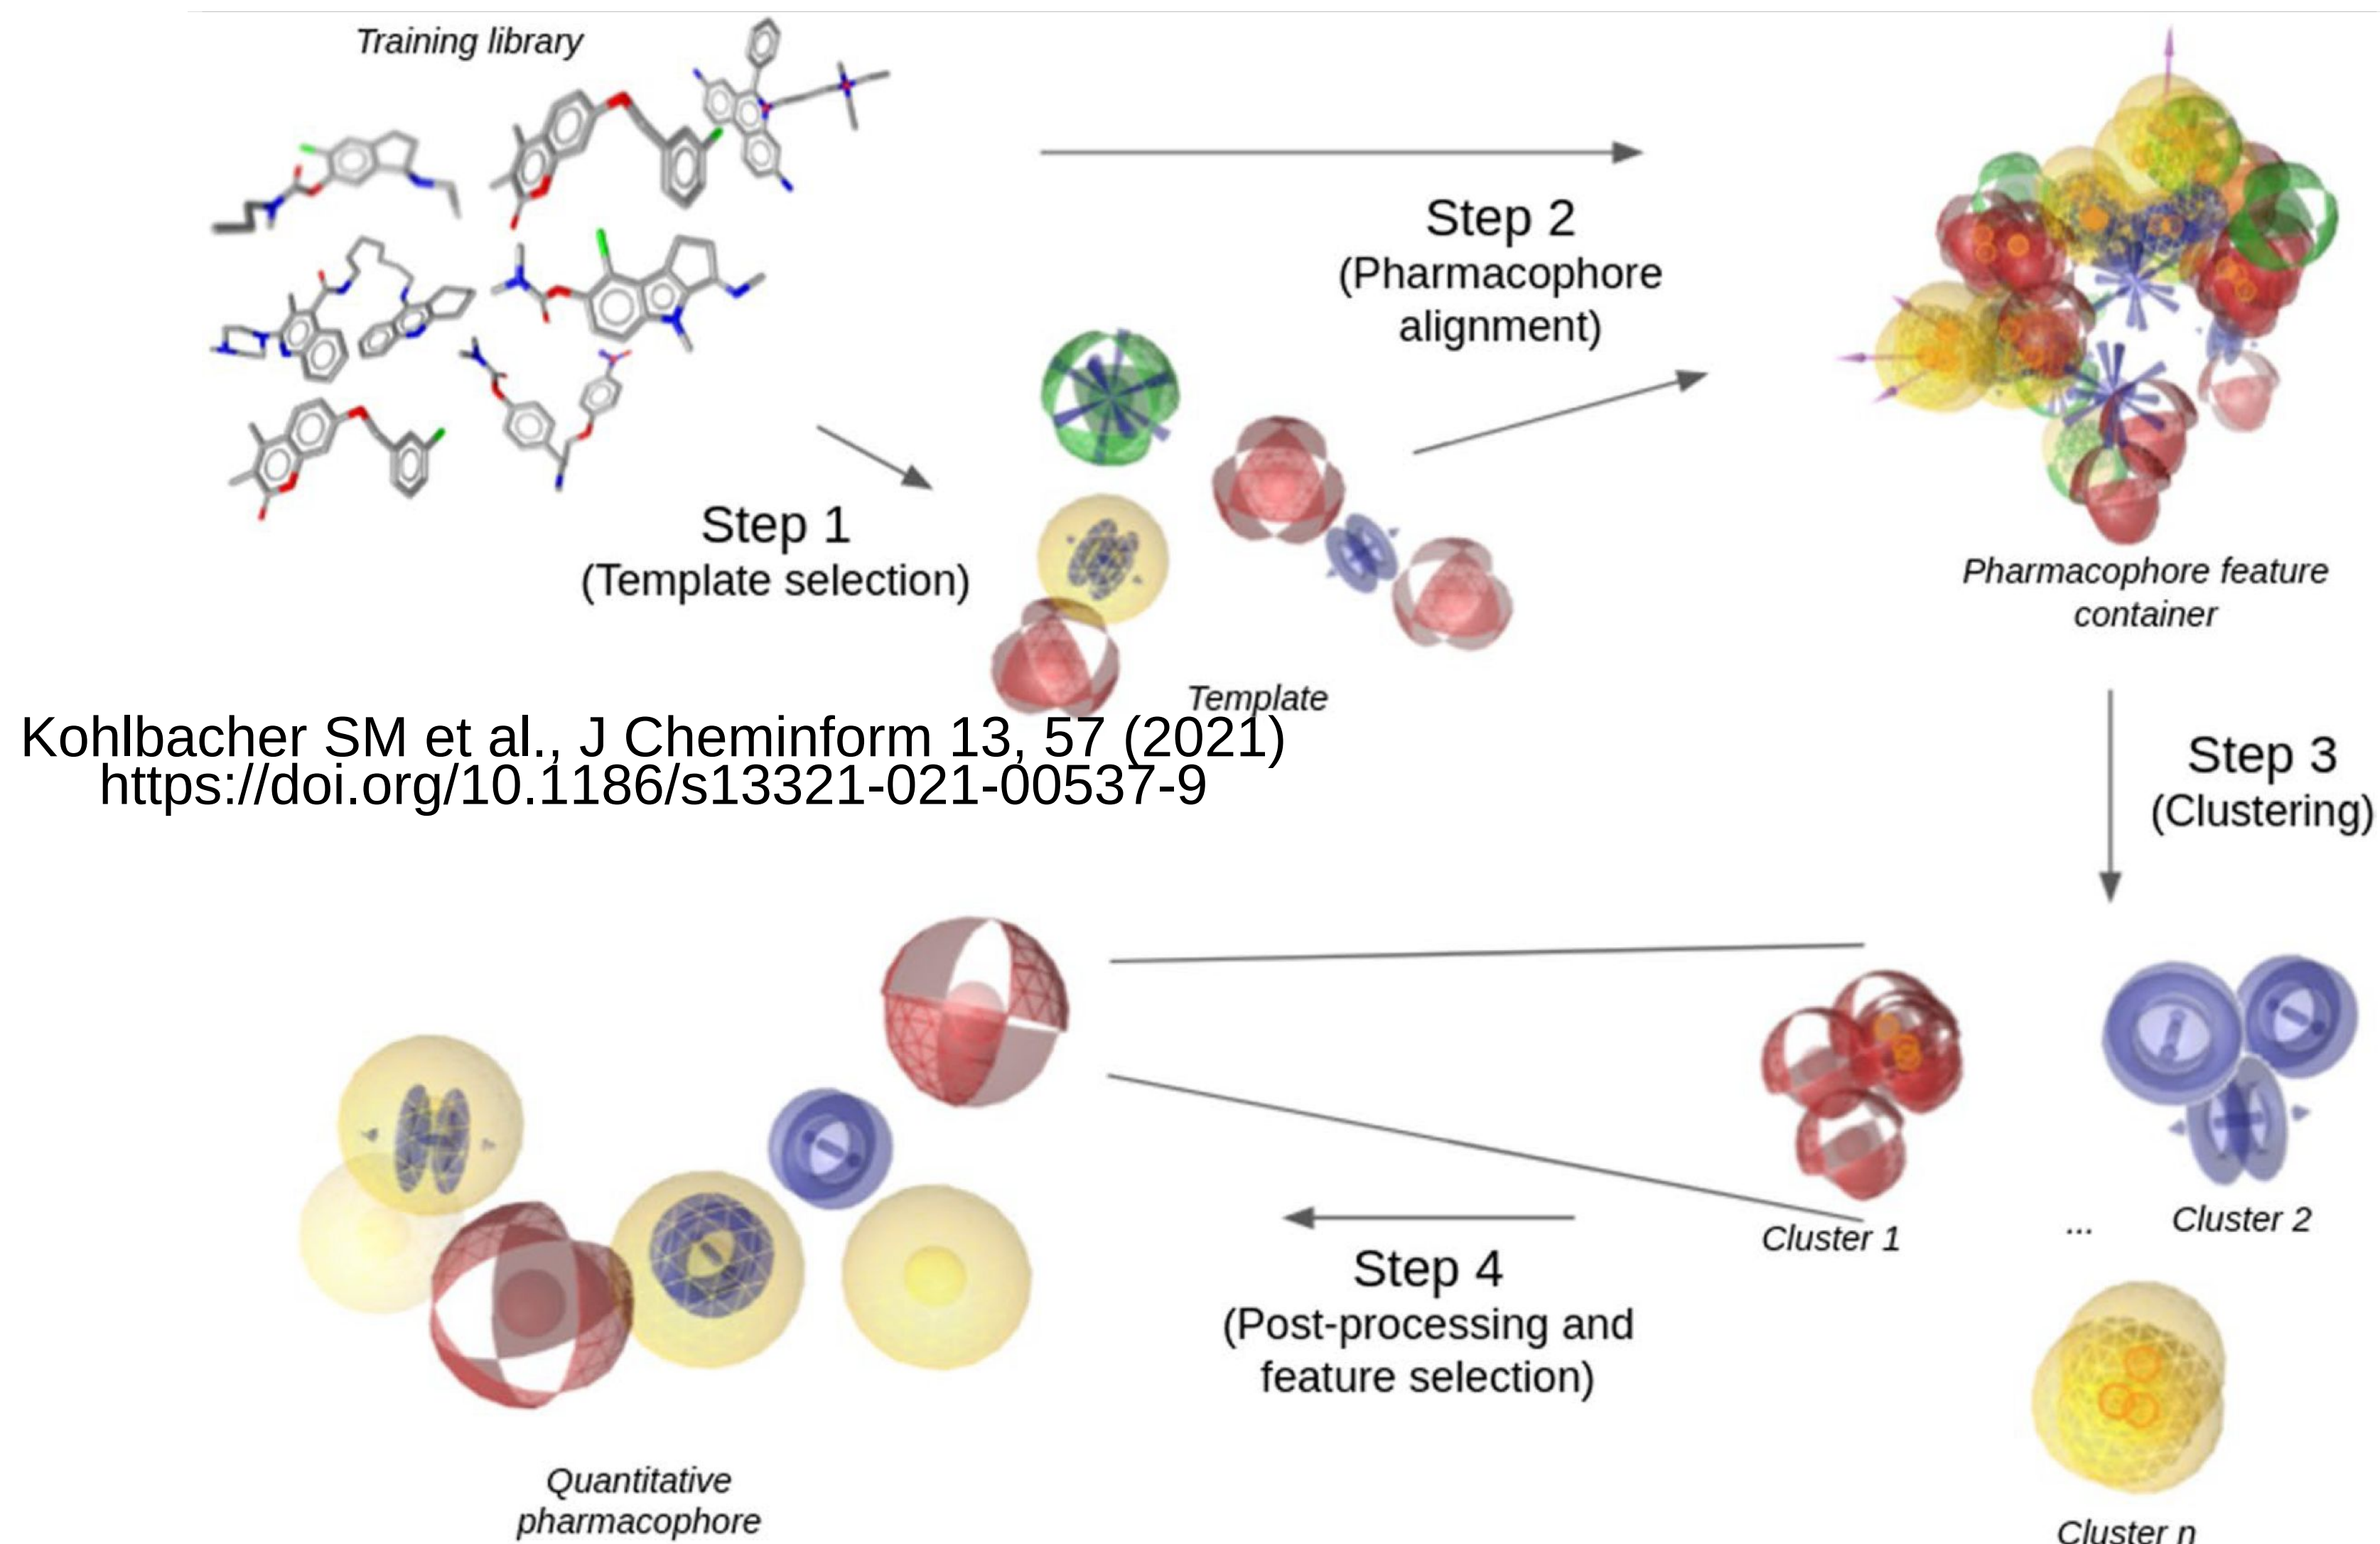

Abstract

QSAR methods are widely applied in the drug discovery process, both in the hit-to-lead and lead optimization phase, as well as in the drug-approval process. Most QSAR algorithms are limited to using molecules as input and disregard pharmacophores or pharmacophoric features entirely. However, due to the high level of abstraction, pharmacophore representations provide some advantageous properties for building quantitative SAR models. The abstract depiction of molecular interactions avoids a bias towards overrepresented functional groups in small datasets. Furthermore, a well-crafted quantitative pharmacophore model can generalise to underrepresented or even missing molecular features in the training set by using pharmacophoric interaction patterns only. This paper presents a novel method to construct quantitative pharmacophore models and demonstrates its applicability and robustness on more than 250 diverse datasets. fivefold cross-validation on these datasets with default settings yielded an average RMSE of 0.62, with an average standard deviation of 0.18. Additional cross-validation studies on datasets with 15–20 training samples showed that robust quantitative pharmacophore models could be obtained. These low requirements for dataset sizes render quantitative pharmacophores a viable go-to method for medicinal chemists, especially in the lead-optimisation stage of drug discovery projects.

Abstract: Pharmacophores are an established concept for the modelling of ligand–receptor interactions based on the abstract representations of stereoelectronic molecular features. They became widely popular as filters for the fast virtual screening of large compound libraries. A lot of effort has been put into the development of sophisticated algorithms and strategies to increase the computational efficiency of the screening process. However, hardly any focus has been put on the development of automated procedures that optimise pharmacophores towards higher discriminatory power, which still has to be done manually by a human expert. In the age of machine learning, the researcher has become the decision-maker at the top level, outsourcing analysis tasks and recurrent work to advanced algorithms and automation workflows. Here, we propose an algorithm for the automated selection of features driving pharmacophore model quality using SAR information extracted from validated QPhAR models. By integrating the developed method into an end-to-end workflow, we present a fully automated method that is able to derive best-quality pharmacophores from a given input dataset. Finally, we show how the QPhAR-generated models can be used to guide the researcher with insights regarding (un-)favourable interactions for compounds of interest.

Abstract

Dissemination of novel research methods, especially in the form of chemoinformatics software, depends heavily on their ease of applicability for non-expert users with only a little or no programming skills and knowledge in computer science. Visual programming has become widely popular over the last few years, also enabling researchers without in-depth programming skills to develop tailored data processing pipelines using elements from a repository of predefined standard procedures. In this work, we present the development of a set of nodes for the KNIME platform implementing the QPhAR algorithm. We show how the developed KNIME nodes can be included in a typical workflow for biological activity prediction. Furthermore, we present best-practice guidelines that should be followed to obtain high-quality QPhAR models. Finally, we show a typical workflow to train and optimise a QPhAR model in KNIME for a set of given input compounds, applying the discussed best practices.

[†]Inte:Ligand GmbH, Mariahilferstrasse 74B/11, A-1070 Vienna, Austria

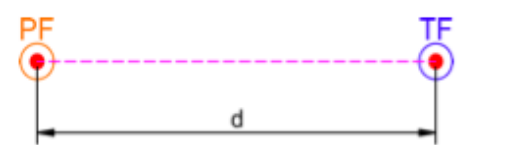

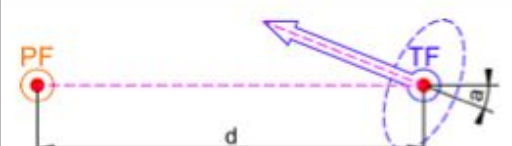

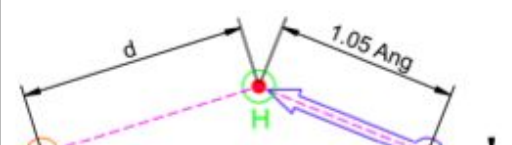

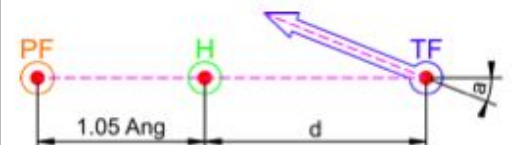

[‡]Department of Pharmaceutical Chemistry, University of Vienna, UZA 2, Althanstrasse 14, 1090 Vienna, Austria

ABSTRACT: In the absence of experimentally derived, three-dimensional structures of receptors in complex with active ligands, it is of high value to be able to gain knowledge about energetically favorable interaction sites solely from the structure of the receptor binding site. For de novo ligand design as well as for lead optimization, this information retrieved from the protein is inevitable. The herein presented method called GRAIL combines the advantages of traditional grid-based approaches for the identification of interaction sites and the power of the pharmacophore concept. A reduced pharmacophoric abstraction of the target system enables the computation of all relevant interaction grid maps in short amounts of time. This allows one to extend the utility of a grid-based method for the analysis of large amounts of coordinate sets obtained by long-time MD simulations. In this way it is possible to assess conformation dependent characteristics of key interactions over time. Furthermore, conformational changes of the protein can be taken into account easily and information thus obtained well-guides a rational ligand design process. A study employing MD trajectories of the oncology target heat shock protein 90 showcases how well our novel approach GRAIL performs for a set of different inhibitors bound to their target protein and how molecular features of the inhibitors are subject to optimization.

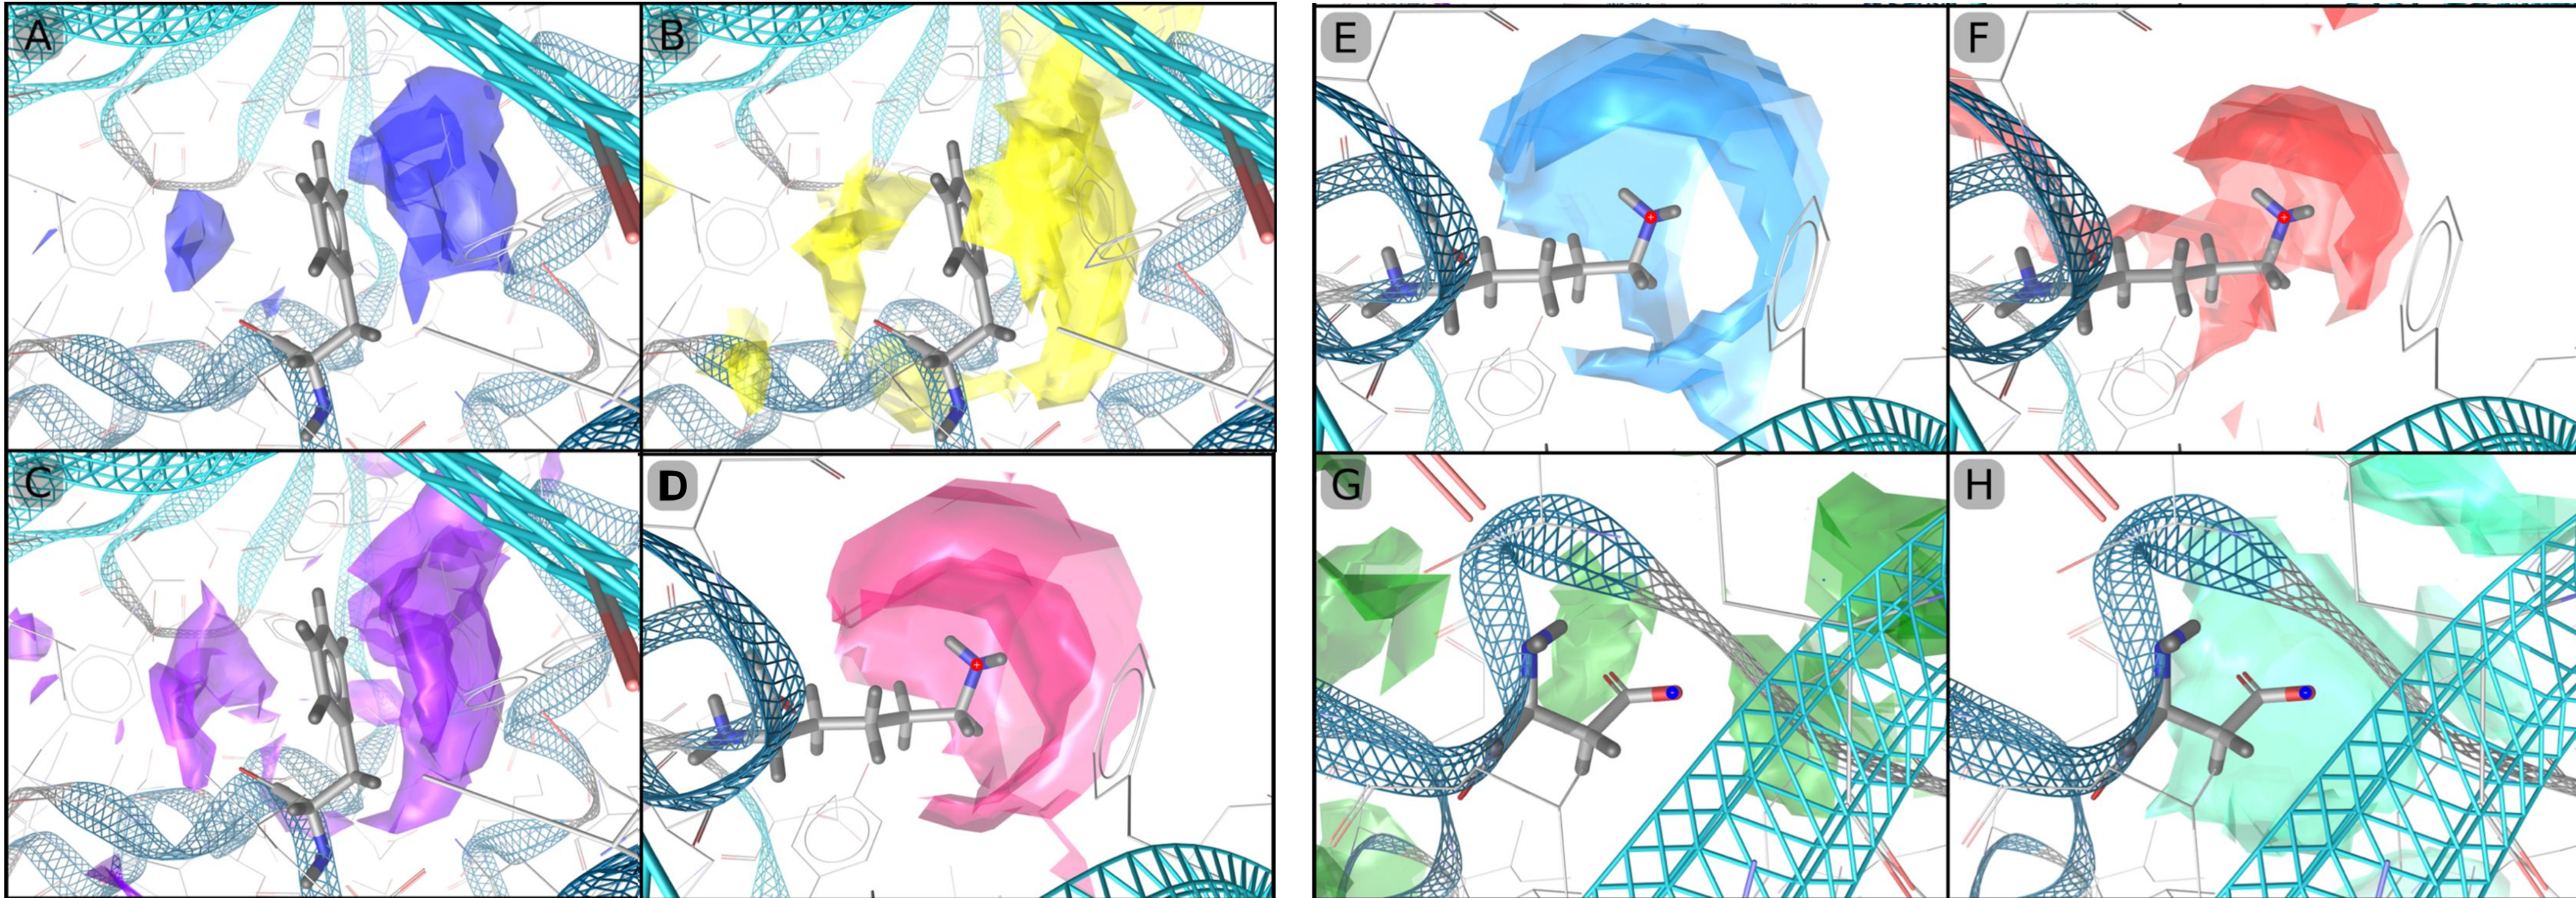

GRAIL Scoring Function

- Grid is defined within the protein binding site, no ligand needed
- At each grid point: Pharmacophore feature probability calculated
- For every interaction type: Optimum distances & angles defined
- Extremely fast, amendable for the analysis of entire MD trajectories
- Script available for CDPKit

Complementary Feature Pair			Interaction Geometry	Distance Scoring Function/ Distance Range	Angle Scoring Function/ Angle Range

WELCOME TO THE NEURODERISK PROJECT

NeuroDeRisk is an “Innovative Medicines Initiative” (IMI2) project aiming to provide novel validated integrated tools for **improving the preclinical prediction** of adverse effects of pharmaceuticals on the nervous system and thus **help to de-risk drug candidates** earlier in the Research and Development phases.

The adverse effects of pharmaceuticals on the central or peripheral nervous systems are poorly predicted by the current *in vitro* and *in vivo* preclinical studies performed during Research and Development (R&D) process. Therefore, increasing the predictivity of the preclinical toolbox is a clear need, and would benefit to human volunteers/patients (safer drugs) and Pharmaceutical Industry (reduced attrition). By **combining top level scientists in neurobiology/toxicology with successful software developers**, the NeuroDeRisk Consortium will aim at tackling three of the most challenging adverse effects: seizures, psychological/psychiatric changes, and peripheral neuropathies.

De-risking Neurotoxicity

Target Based Approach

- Seizure Risk / Pharmacology
- GABA-A Antagonist
- GABA-A NAM
- GABA-A Channel Blocker
- GABA-A PAM
- GABA-A Agonist
- GABA-A Neurosteroid

Structure-Based Modeling

Outcome Based Approach

- Suicidal Ideation
- Drugs associated with reported outcomes (pharmacovigilance)
- RNA Editing (Alcediag)

Ligand-Based Modeling

De-risking Neurotoxicity

GABA-A orthosteric site, channel SB-modeling examples

GABA-GS-Agonist
(PDB ID:6huj)

Bicuculline-GS-Antagonist
(PDB ID:6huk)

Picrotoxinin-Channel
(PDB ID:6huj)

De-risking Neurotoxicity

Can we identify chemical features in 3D-space associated with suicidal ADEs?

- Outcome Based Approach – No Target
- Suicidal Ideation (5 terms)
- 1492 drugs with suicidal annotations from FAERS, Meta ADEDB and NIH databases (pharmacovigilance)
- Clustering; > 45 LB models created and tested
- Models also generated using confidential experimental data from Alcediag
- Editox – unambiguous IFN α like RNA editing profiles (Alcediag)

Name	T	#	Matching Features
Bifeprunox		2	■ ■ ■ ■ ■ ■
Hydralazine		1	■ ■ ■ ■ ■ ■
Reserpine		3	■ ■ ■ ■ ■ ■
Rimonabant		1	■ ■ ■ ■ ■ ■
Ketoconazole		5	■ ■ ■ ■ ■ ■
Sertindole		3	■ ■ ■ ■ ■ ■

Clomipramine		5	■ ■ ■ ■ ■ ■
Diphenhydramine		1	■ ■ ■ ■ ■ ■
Fluoxetine		2	■ ■ ■ ■ ■ ■
Nortriptyline		3	■ ■ ■ ■ ■ ■

Promising results with the IFN α like RNA editing (Editox) datasets

De-risking Neurotoxicity

- 60 3D-pharmacophore models have so far been incorporated and deployed in the NeuroDeRisk in silico toolbox and more are currently developed

Neurotoxicity Off Target Prediction

- Profile chemical structures (queries) using 3D-pharmacophore models
- Both models and LigandScout algorithms for profiling are encoded into the NeuroDeRisk IL Profiler node
- Multiple inputs supported including a 2D-editor
- Visualisation and export in different formats: PNG, CSV, XLS, SDF, etc.

Pharmacophores: 30 Molecules: 9

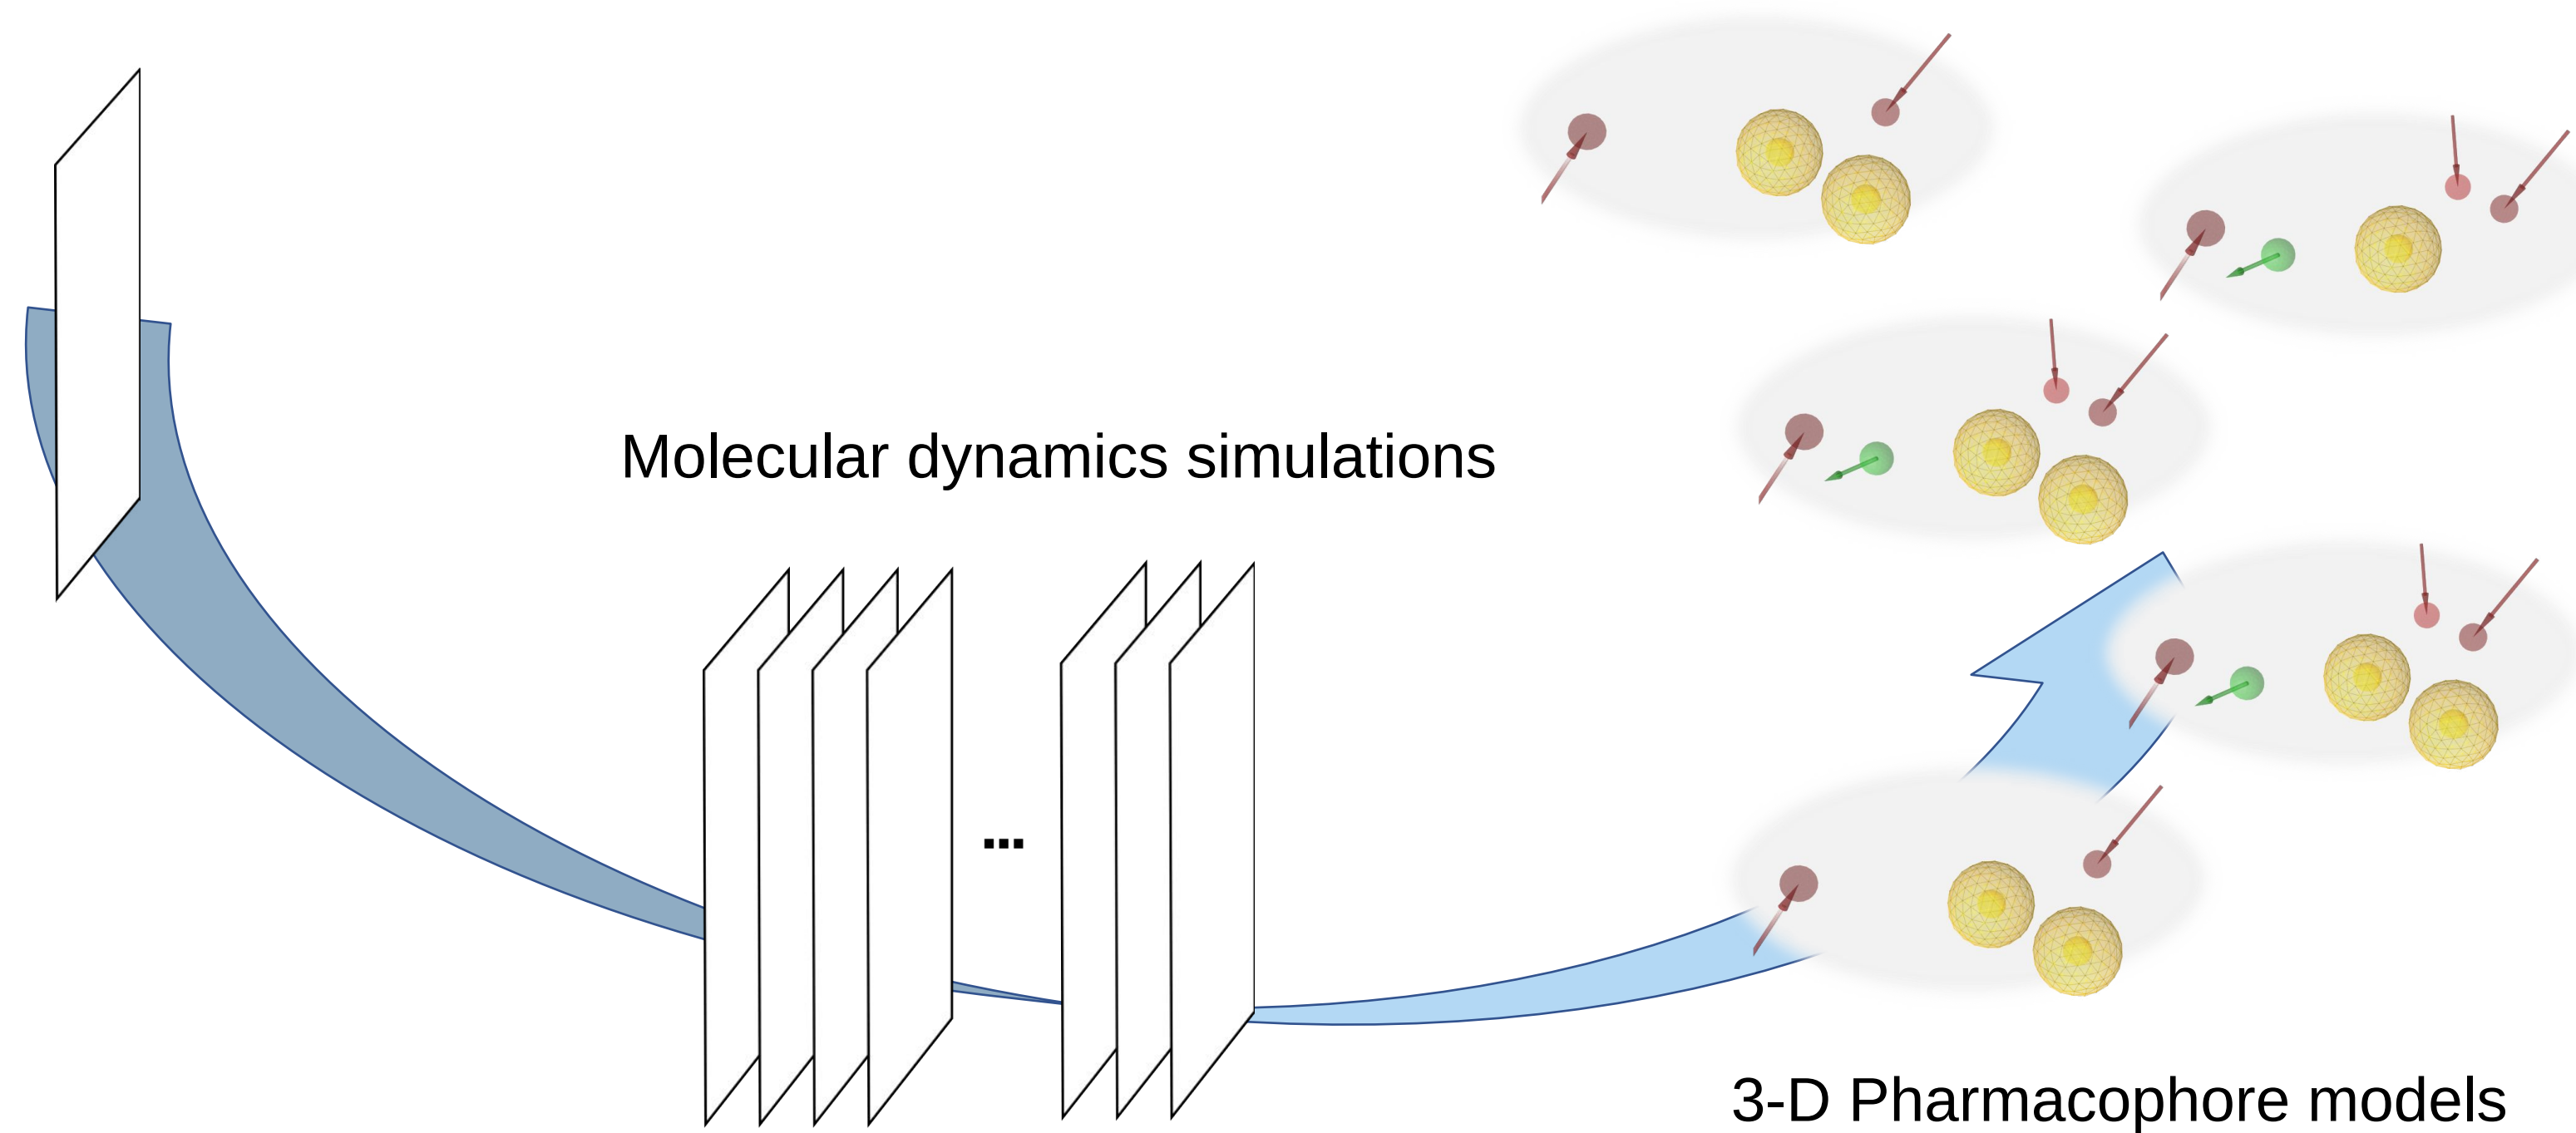

- Next generation pharmacophore models are ready for the most difficult challenges in computer aided molecular design
- Highly useful for hit identification & prioritisation
- Amendable for high precision virtual screening in exa scale libraries
- Most comprehensive for medicinal chemistry guidance
- Take into account dynamic effects in binding kinetics and translate directly to design
- Better lead structures void of toxicity risks

Understanding MD Trajectories

- Define a new way to analyse MD trajectory big data:
Hierarchical pharmacophore graph representation

Crystallographic structure

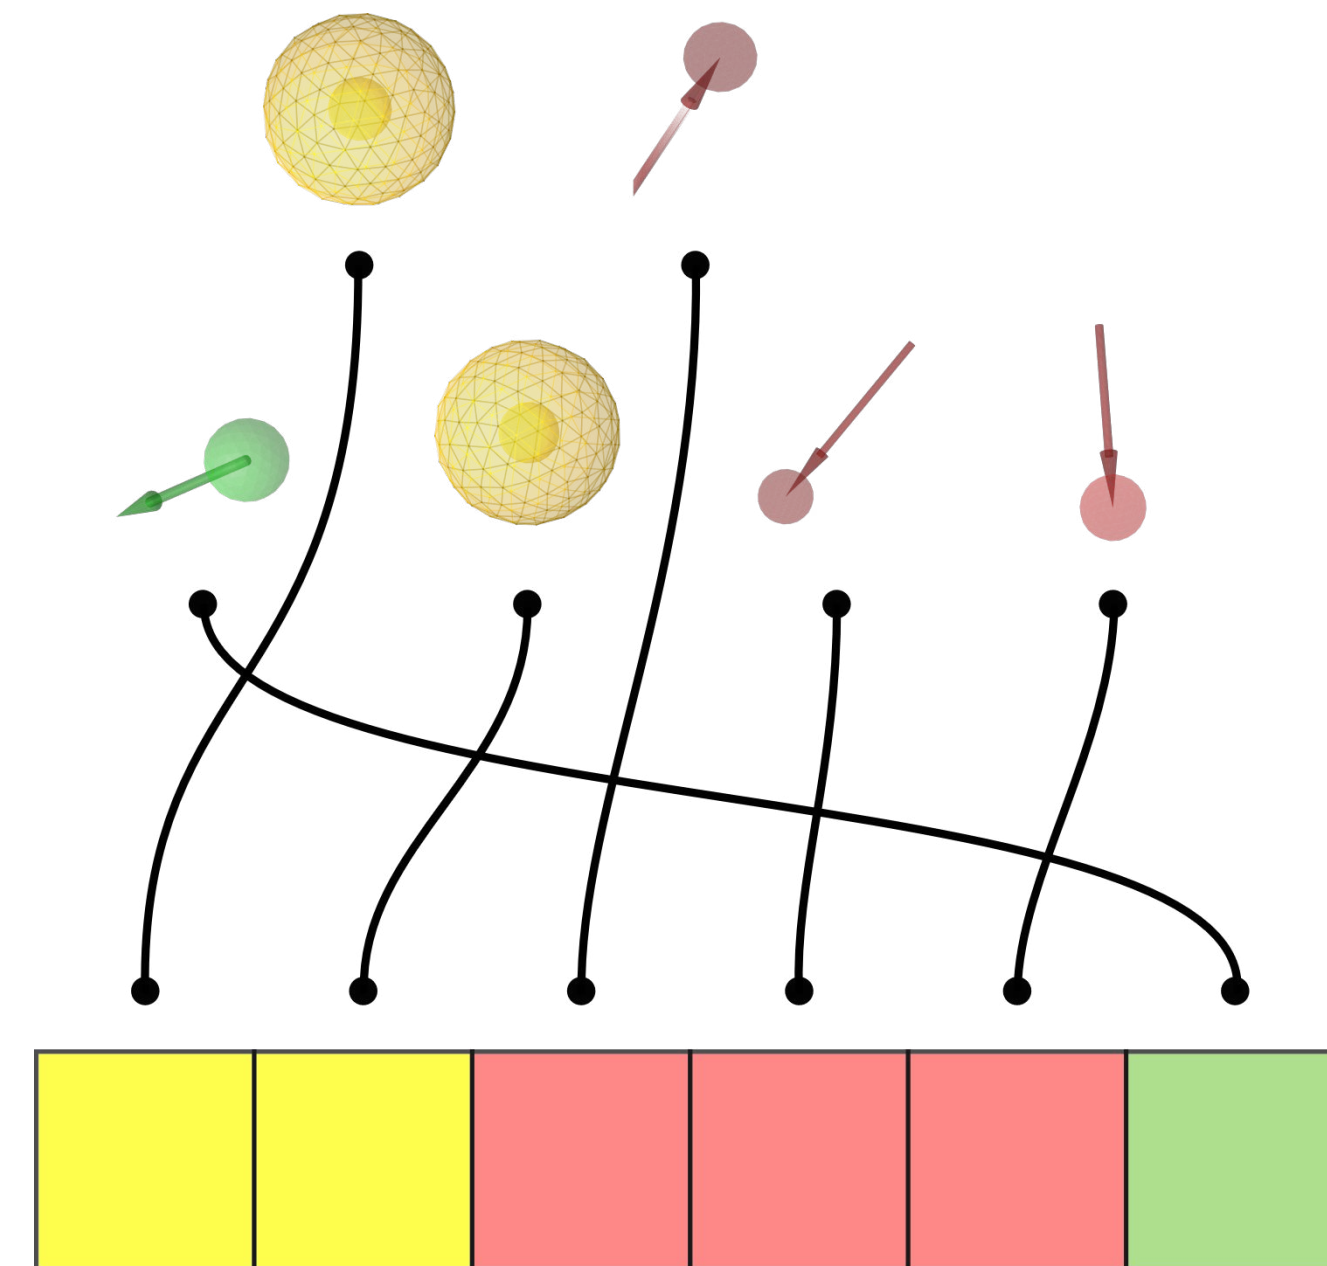

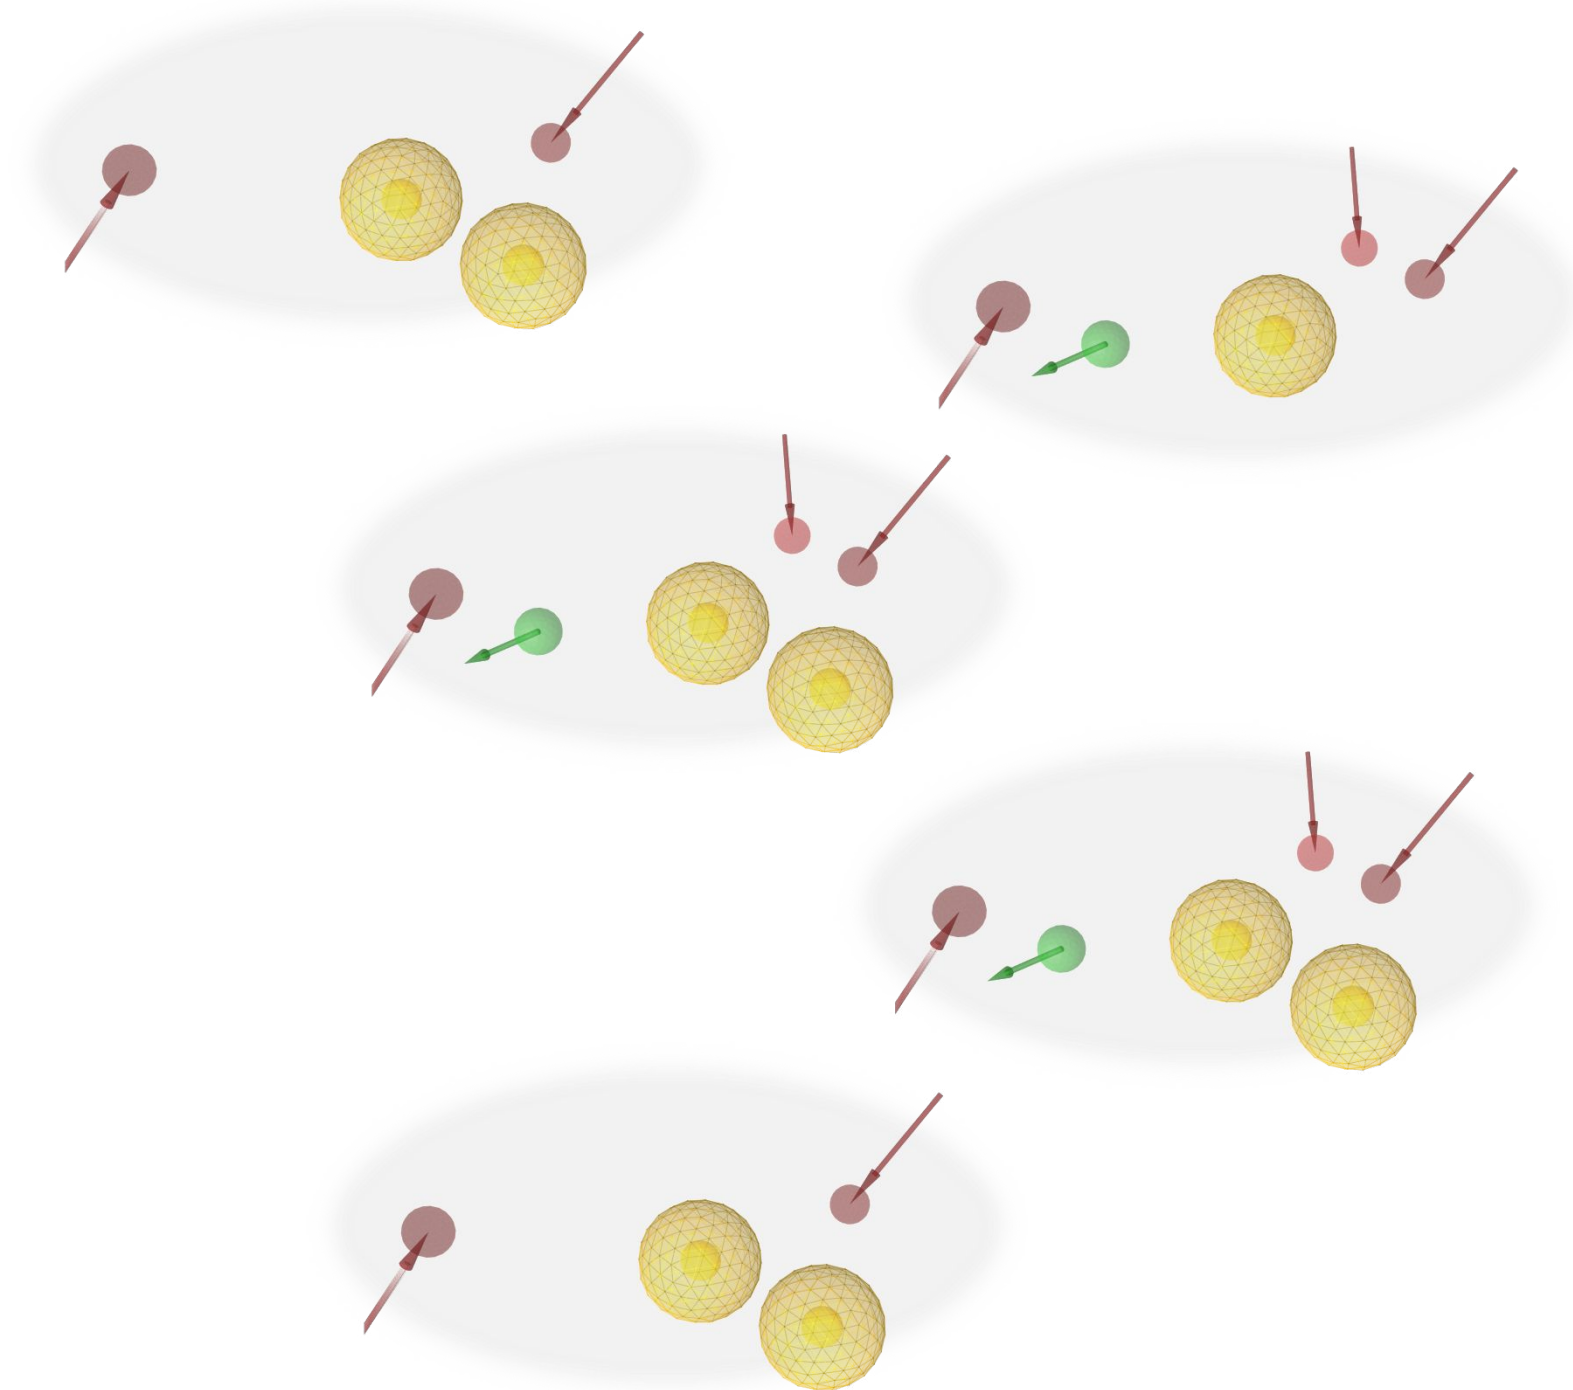

Garon A et al., Models. Front. Mol. Biosci. 7:599059. doi: 10.3389/fmolb.2020.599059

MD P4 Relationship Analysis

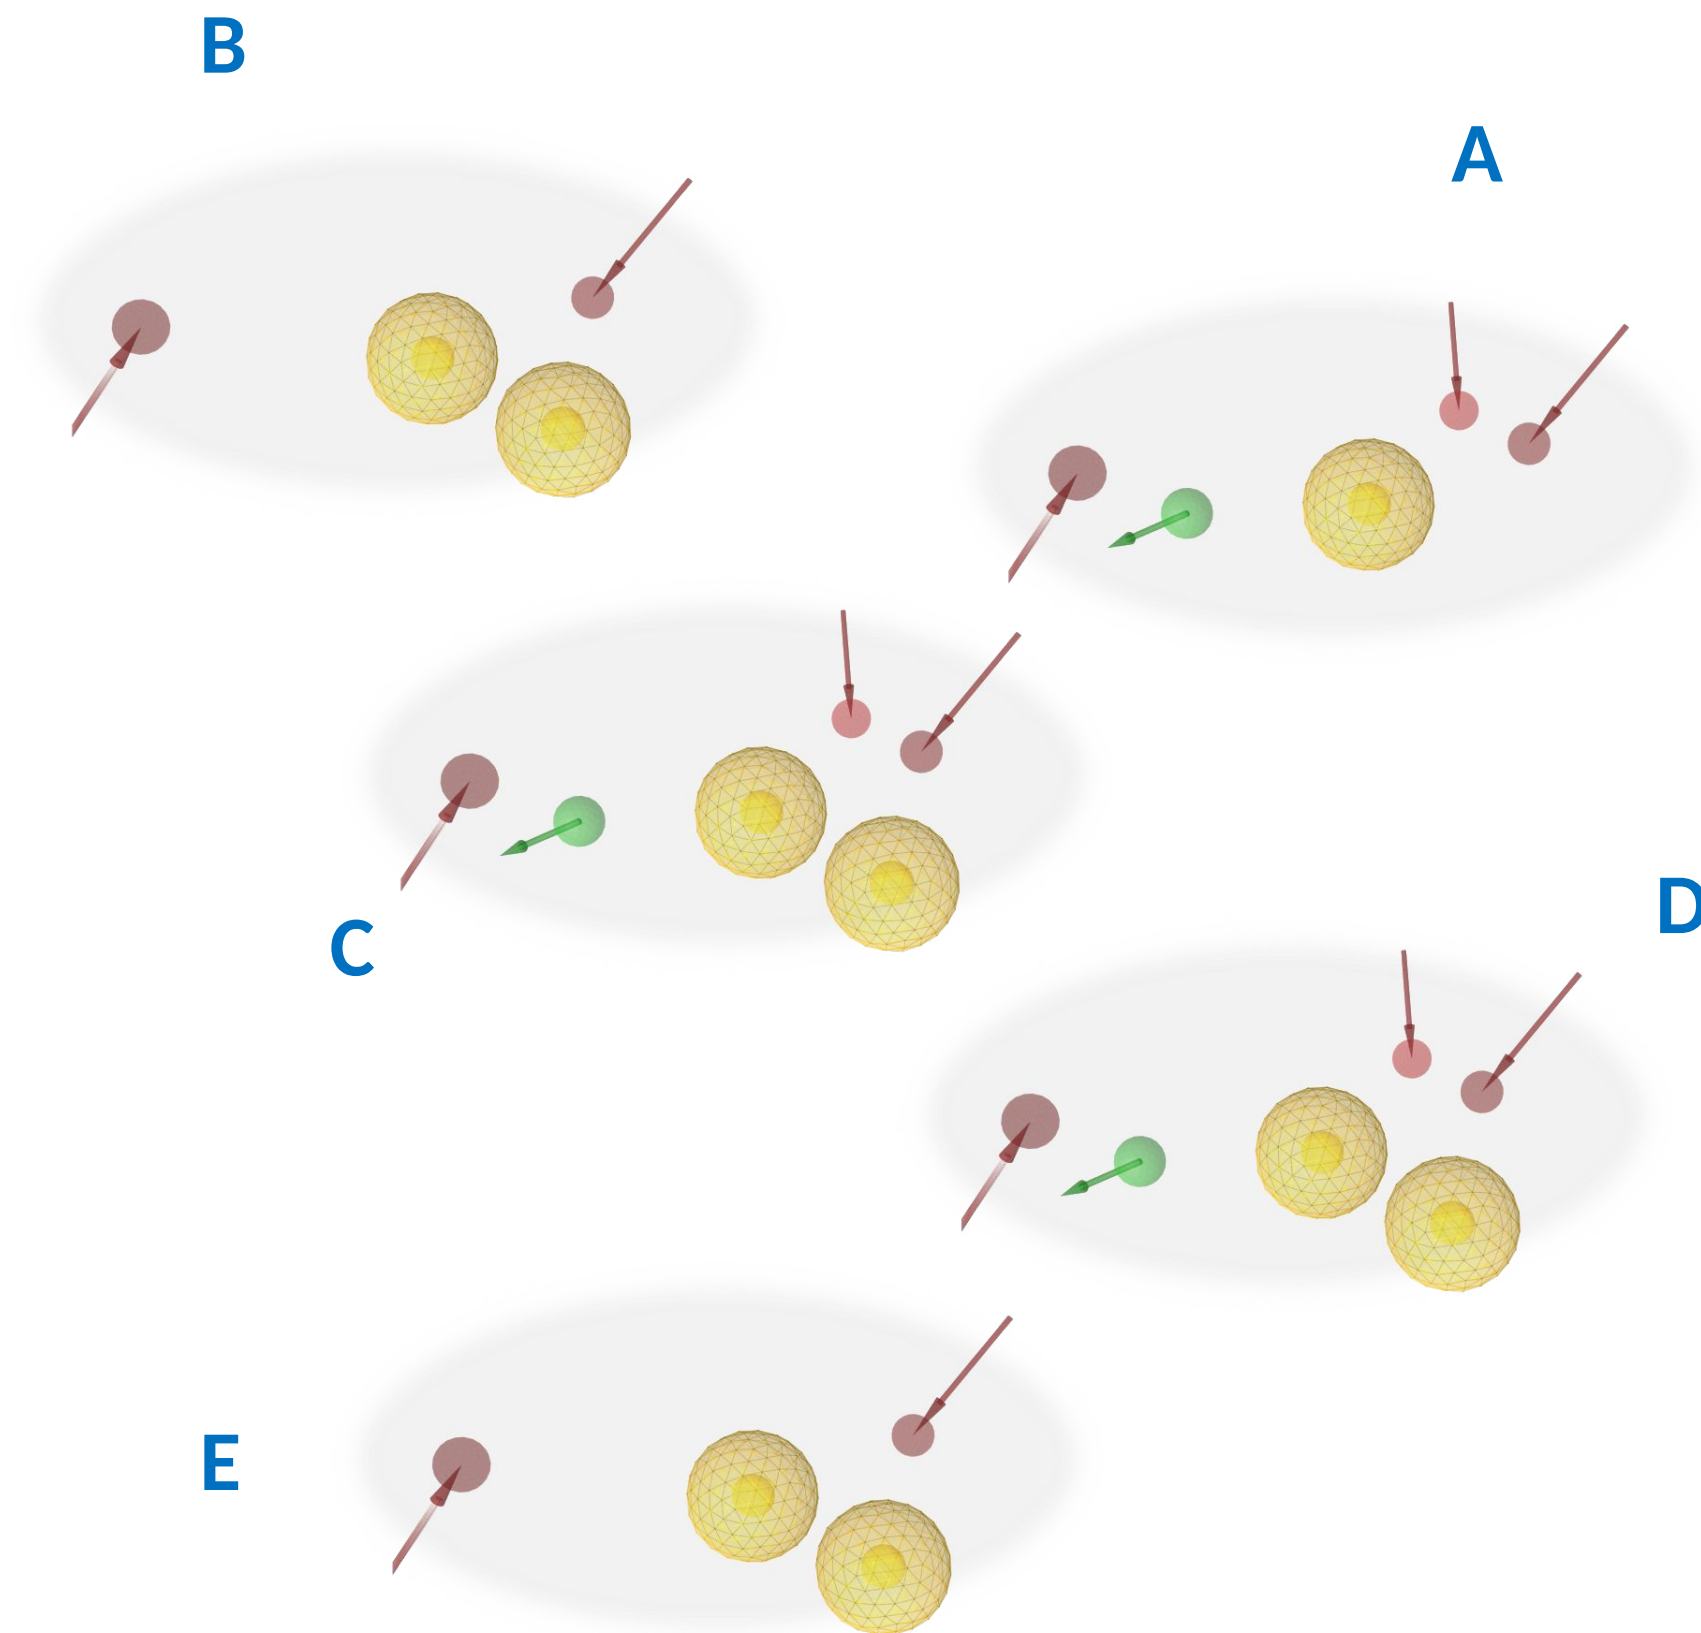

- Hierarchical network of pharmacophores
- Layers are organised by multidimensional scaling
 - each node represents one unique pharmacophore model
 - nodes are sorted to best represent the distance between them
 - fingerprint space reduced into one dimension
 - distance between nodes defined by Manhattan metrics

P4 Model Vector Representation

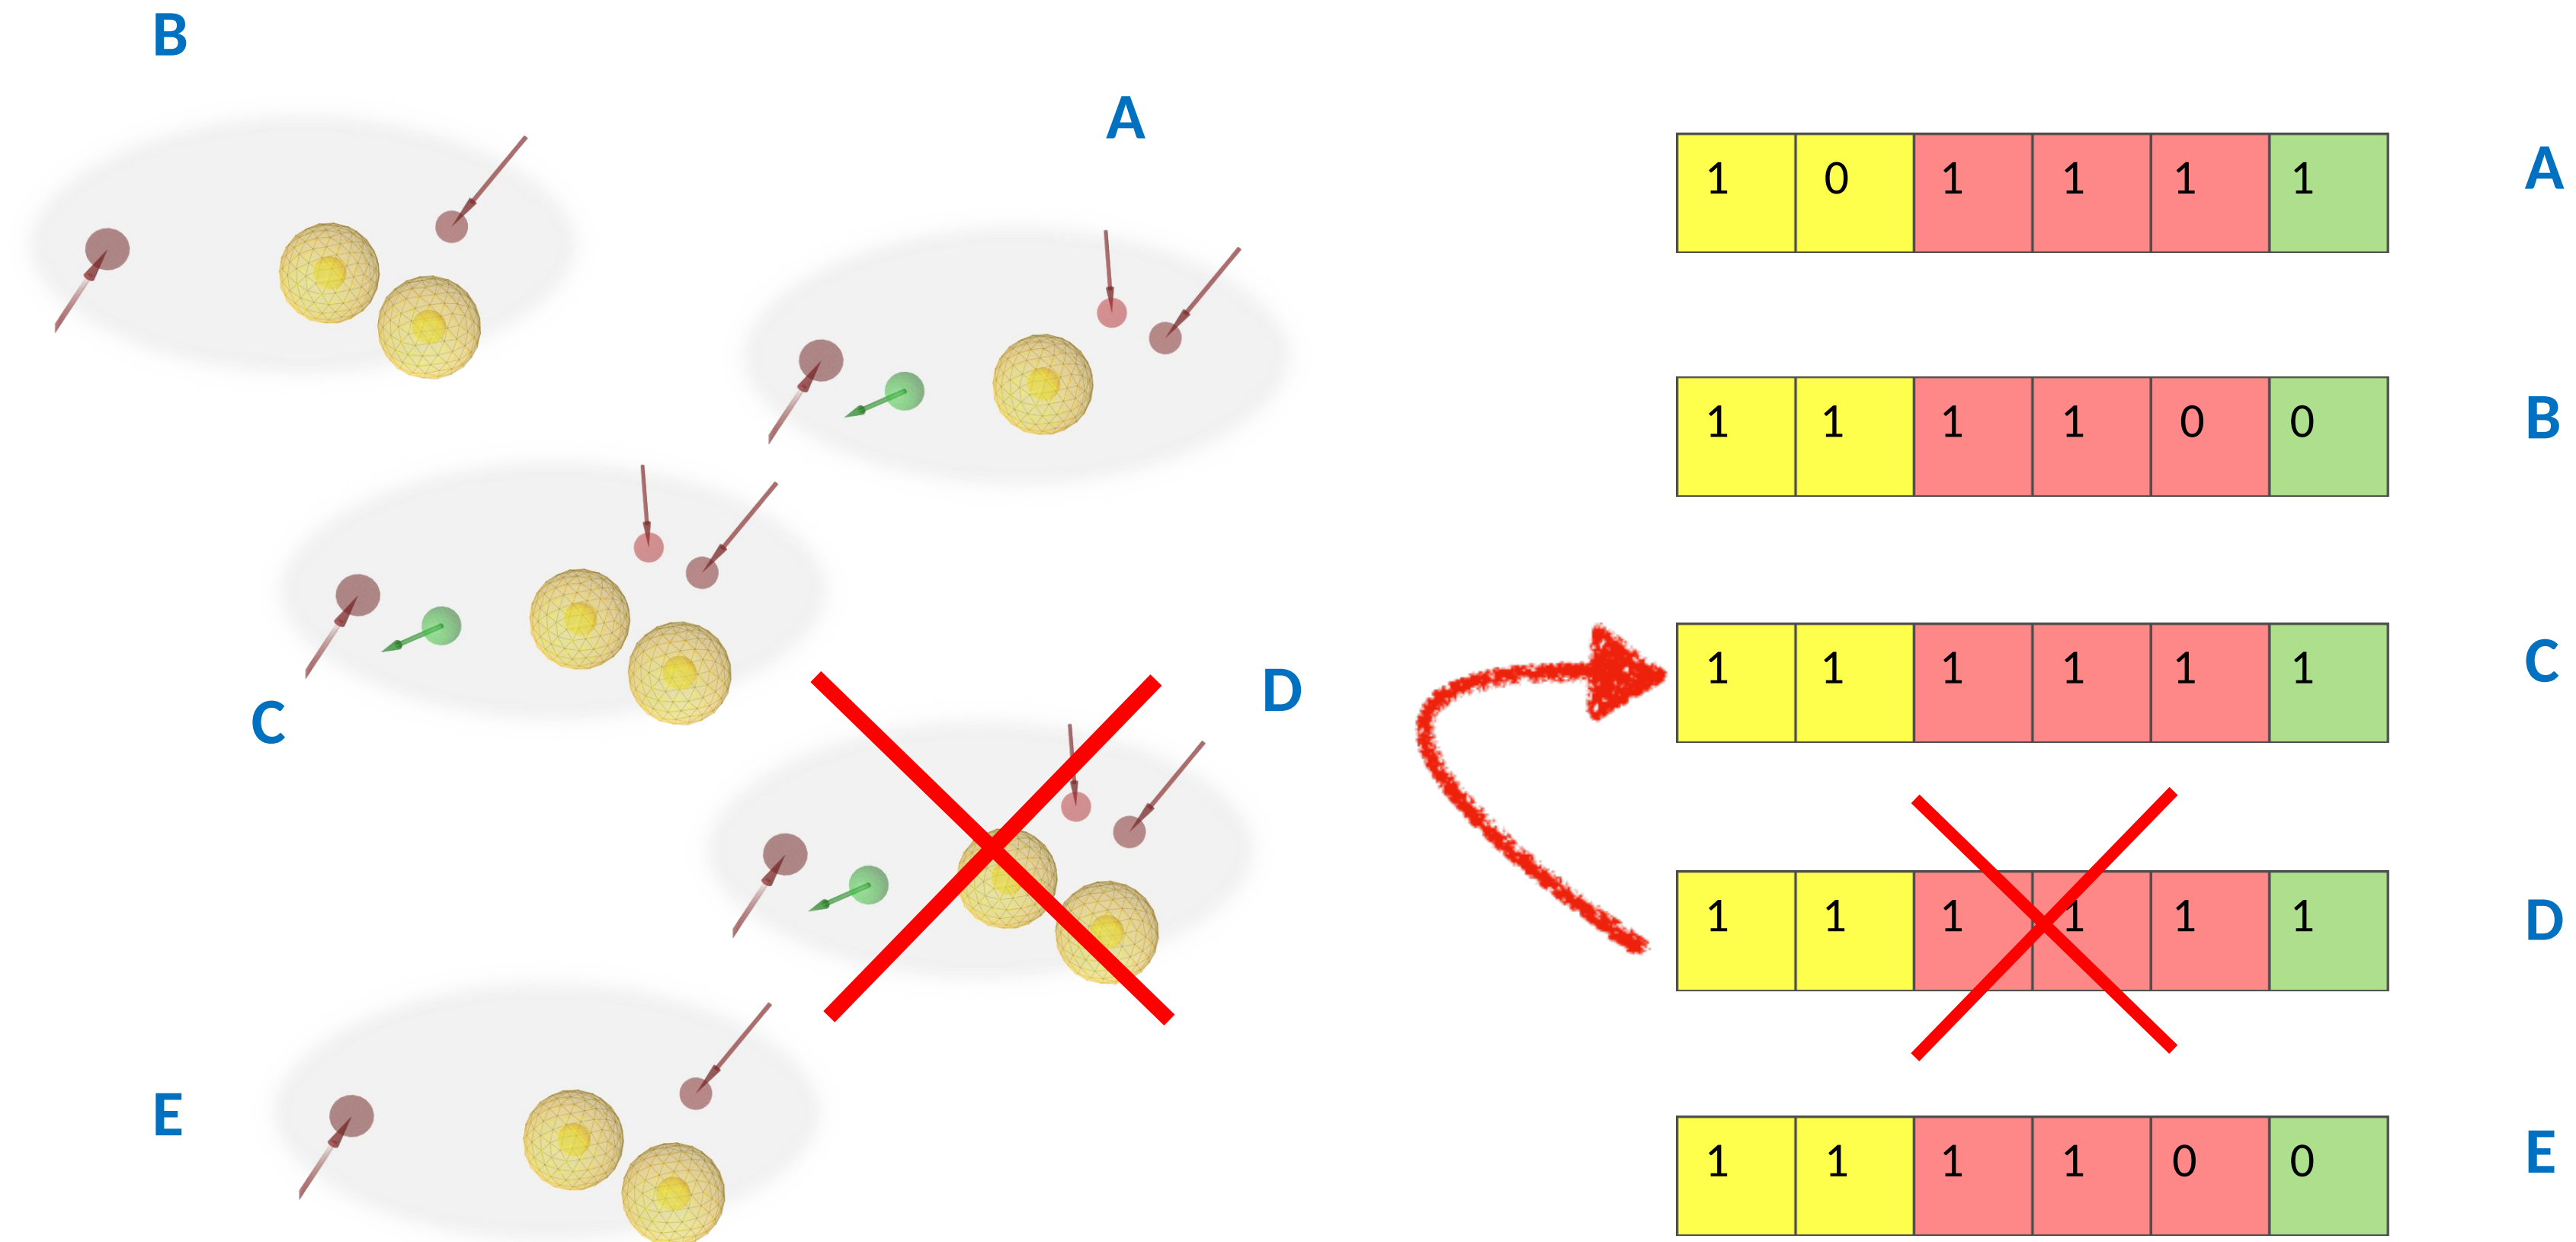

P4 Model Vector Representation

1	0	1	1	1	1	A
1	1	1	1	0	0	B
1	1	1	1	1	1	C
1	1	1	1	1	1	D
1	1	1	1	0	0	E

Glucokinase Case Study

- Analysis of binding modes of ligands in human glucokinase: Difference between active & inactive form

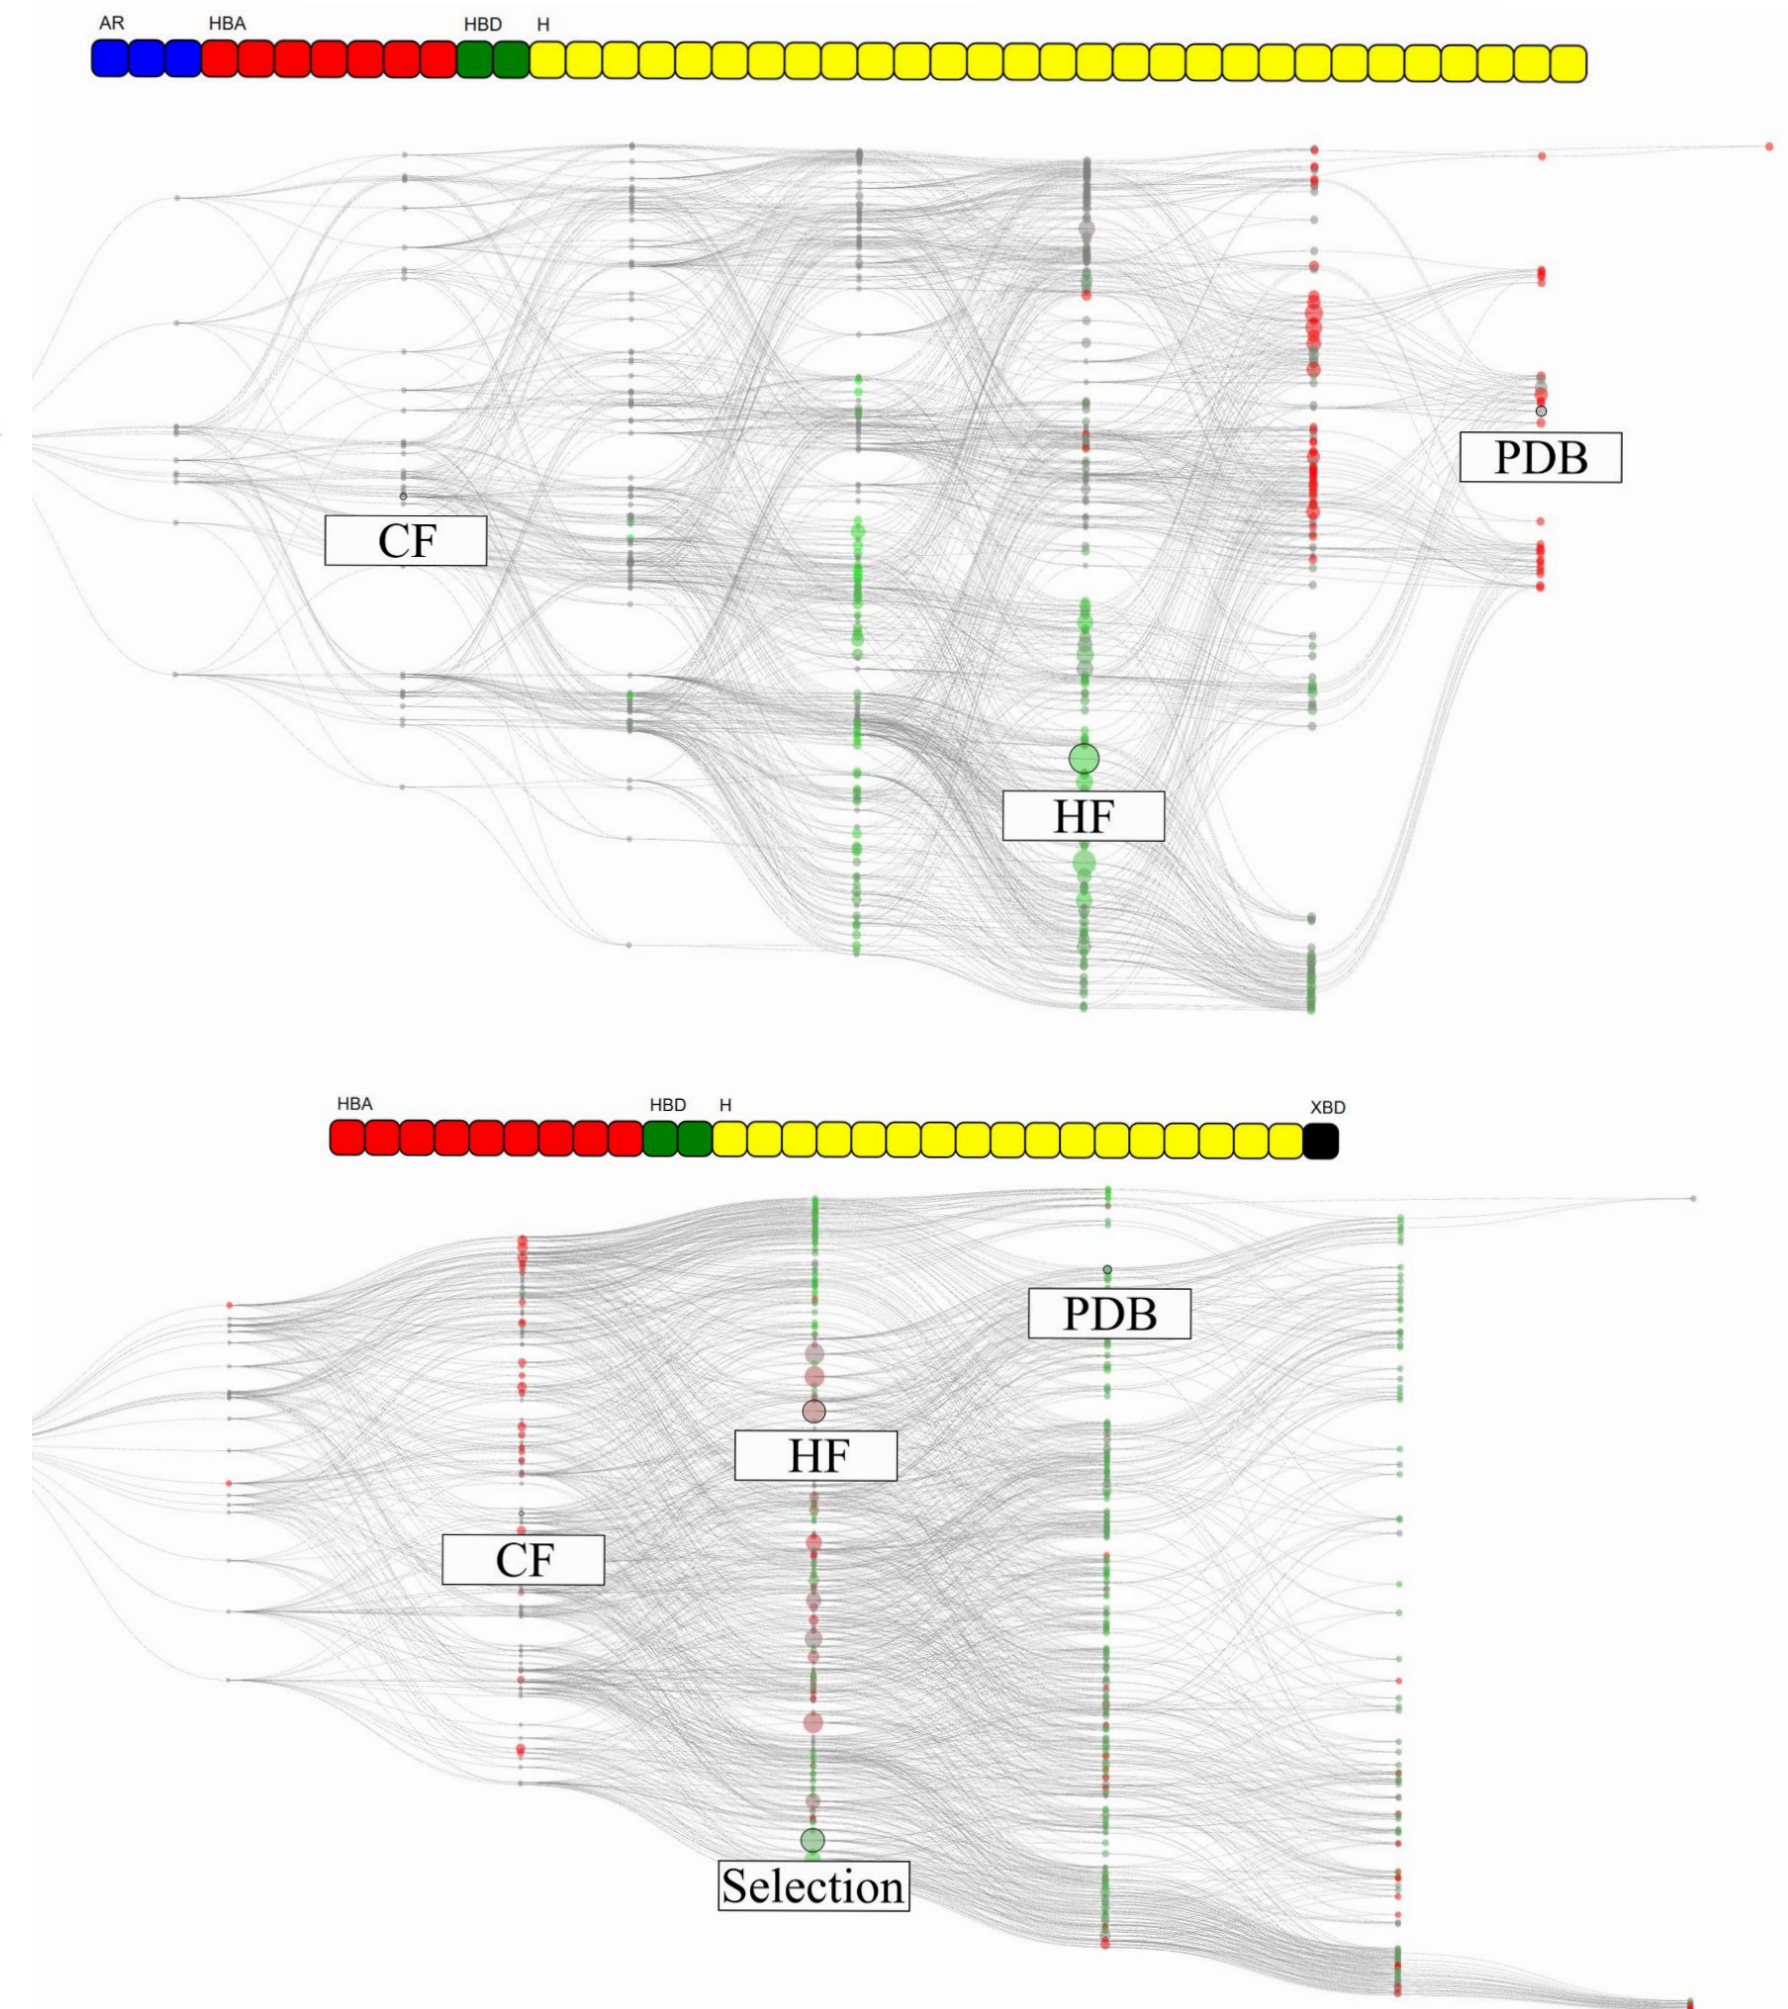

Garon A et al., Models. Front. Mol. Biosci. 7:599059. doi: 10.3389/fmolb.2020.599059

Glucokinase Case Study

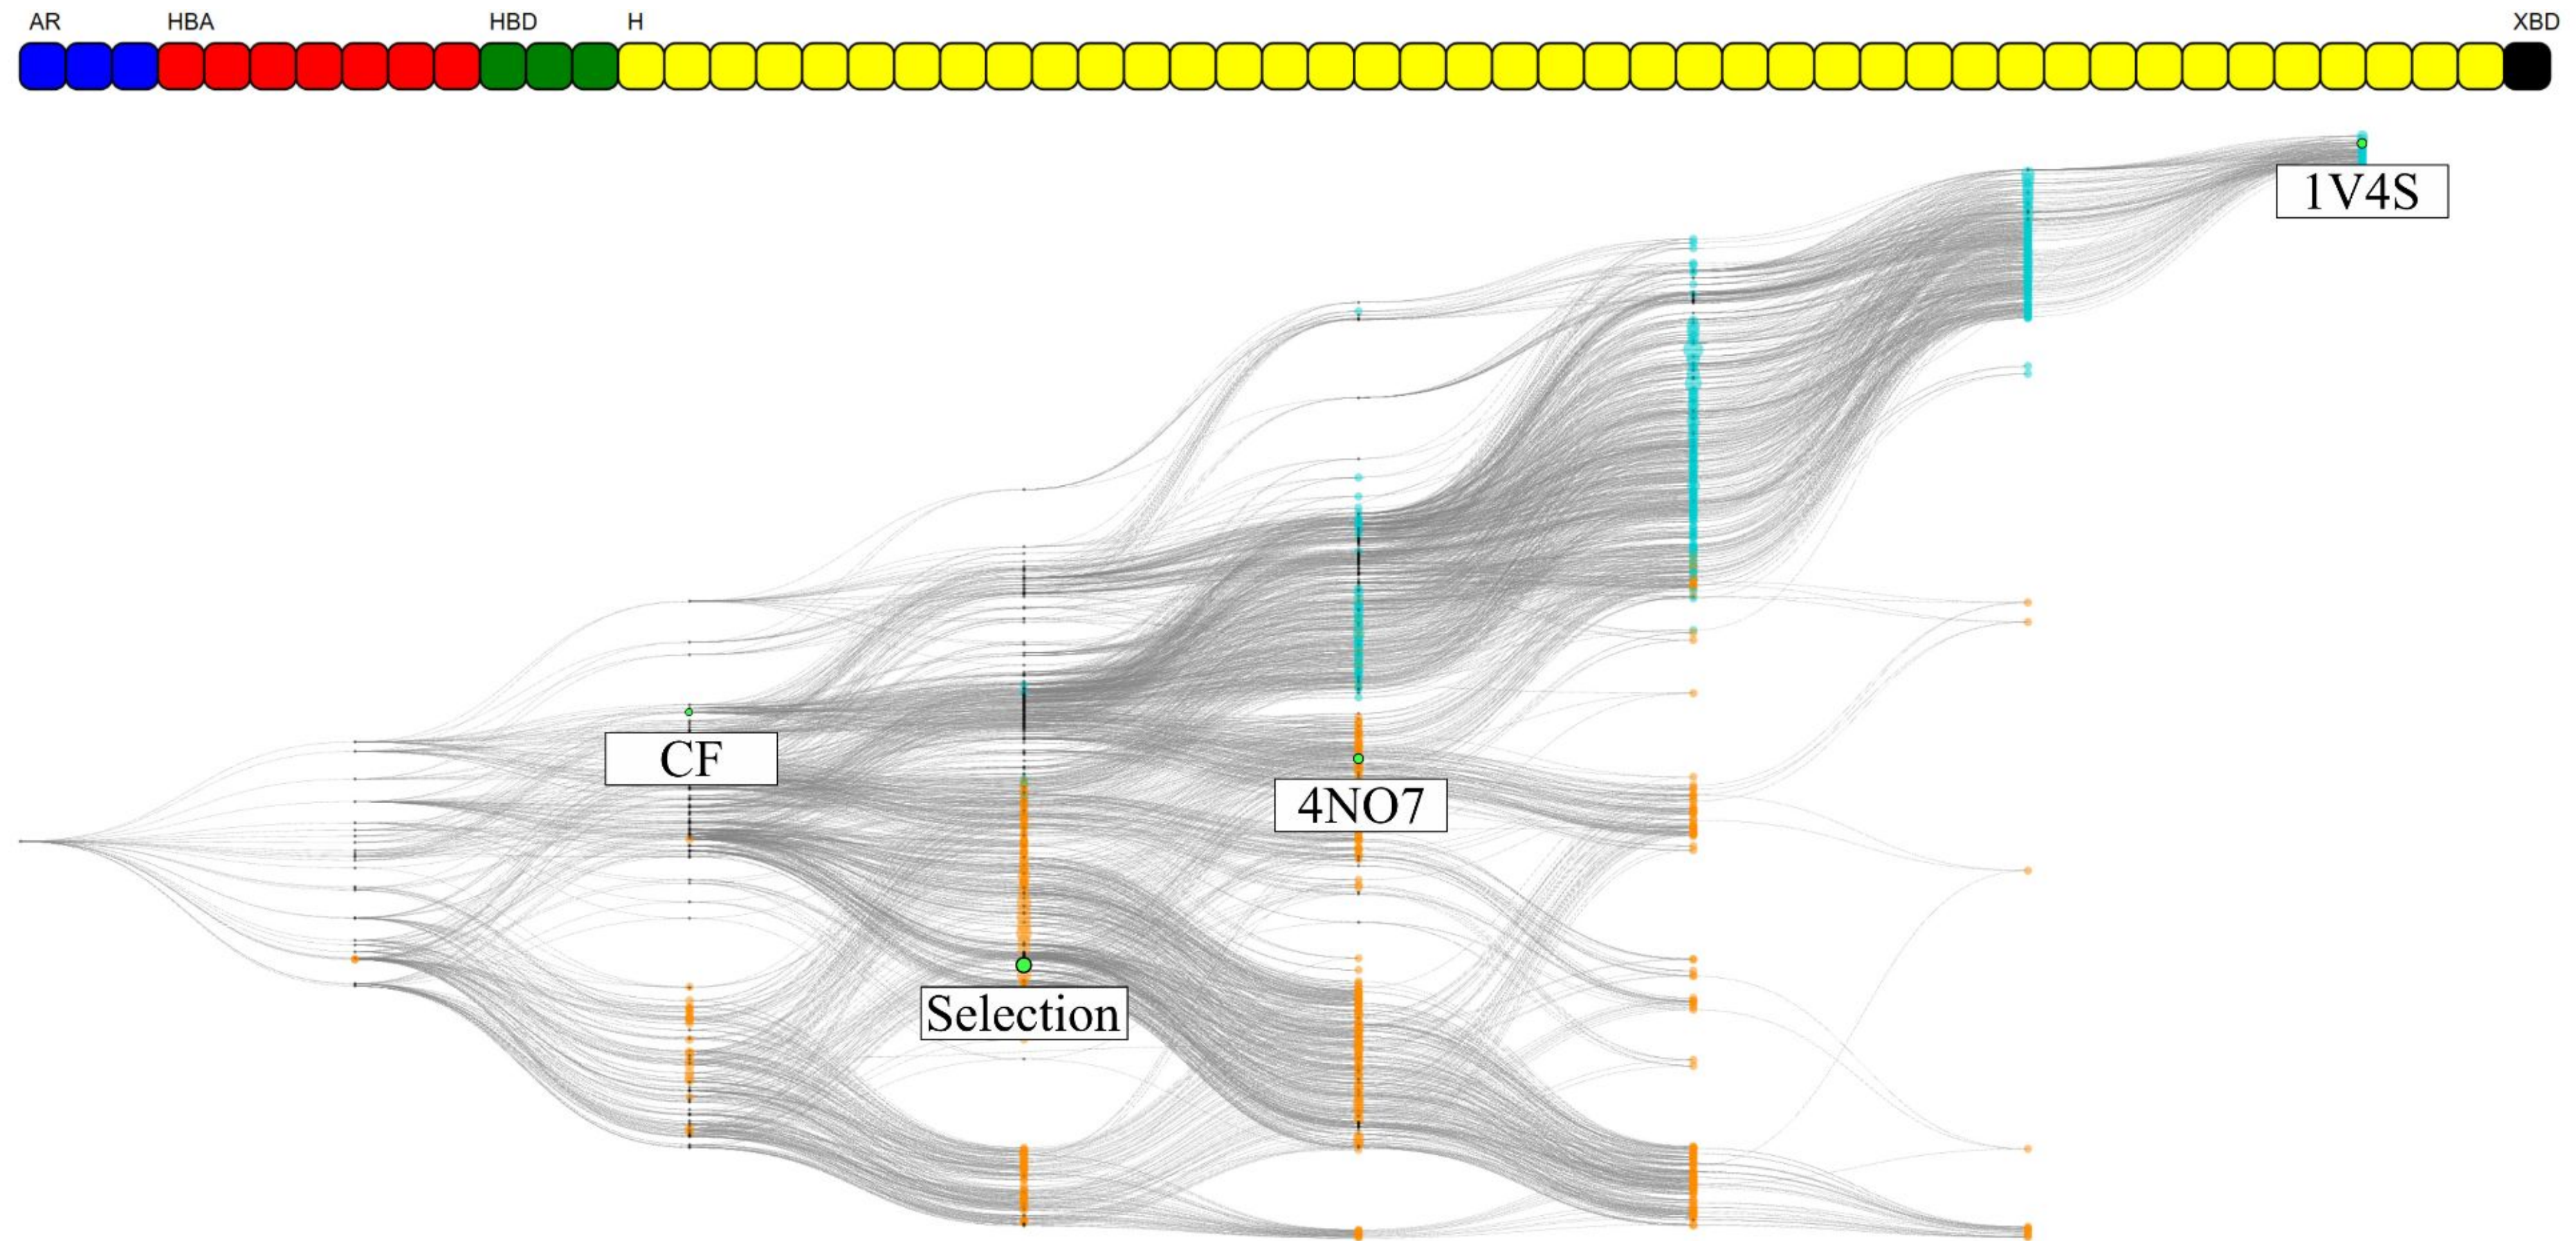

1v4s - inactive form

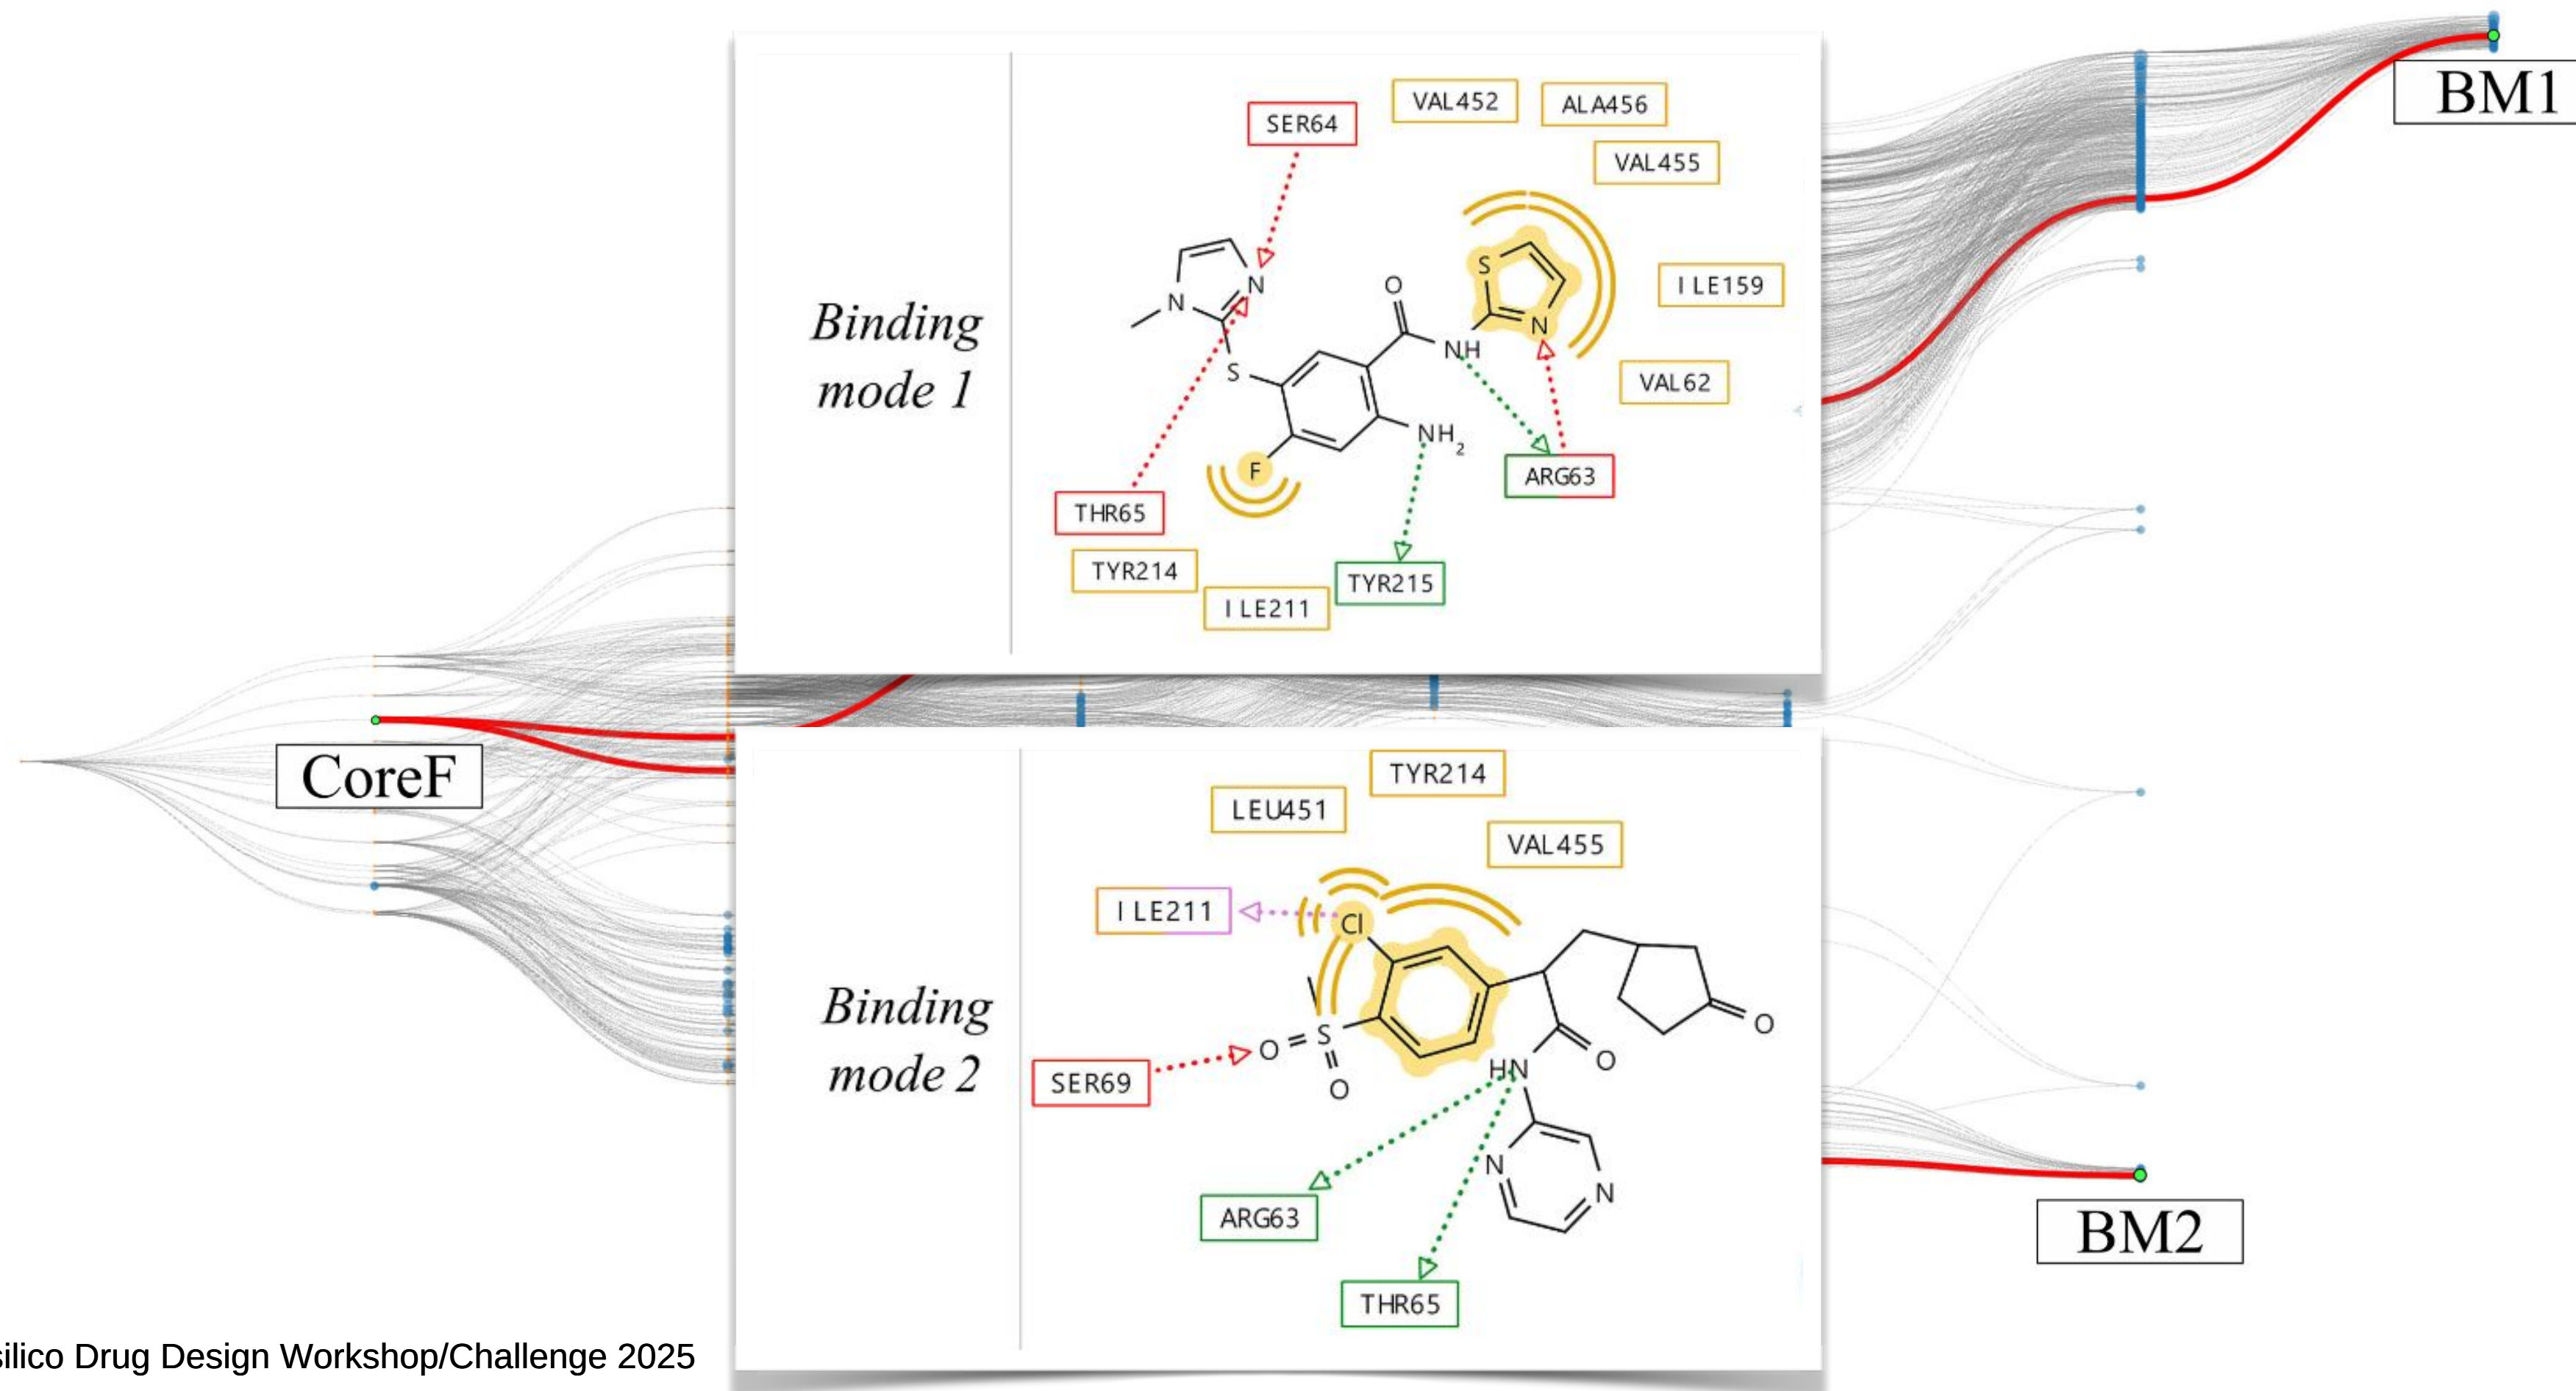

4no7 - active form

Glucokinase Case Study

Glucokinase Case Study

Conclusions

- Our pattern recognition-base pharmacophore technique is superior to all previous P4 methods with respect to speed and accuracy
 - ➔ Highly useful for hit identification
- The pharmacophore interaction analysis concept is no more limited to static observation but is available in a convenient dynamic approach
 - ➔ Highly useful for lead structure optimisation

LigandScout XT

The screenshot displays the LigandScout XT software interface. The main window is titled "LigandScout-5.0_pre-alpha2" and features a toolbar with various icons for navigation and analysis. The interface is divided into several panels:

- Left Panel:** A project tree for "Project: LS-Default-Project" showing a "pdb-download" folder with four macromolecules: 1KE5, 1KE7, 1KE8, and 1KE6. Each macromolecule has associated "Water" and "Backbone" components.
- Center Panels:** Four 3D molecular models of protein-ligand complexes, labeled "Macromolecule: 1KE5", "Macromolecule: 1KE6", "Macromolecule: 1KE8", and "Macromolecule: 1KE7". Each model shows a protein structure in cyan and a yellow ligand.
- Right Panel:** Metadata for the selected structure, including a "PDB 4-letter code" field with a "Download/Renew" button. Below this, the "4-Letter ID: 1KE8" is shown, along with the title "CYCLIN-DEPENDENT KINASE 2 (CDK2) COMPLEXED WITH 4-[[2-OXO-1,2-DIHYDRO-3H-INDOL-3-YLIDENE)METHYL]AMINO)-N-(1,3-THIAZOL-2-YL) BENZENESULFONAMIDE" and a resolution of "2.0".
- Bottom Right Panel:** A "Molecule 2D" view showing four chemical structures corresponding to the ligands in the center panels, labeled with their IDs: (1KE7) [A] LS3299, (1KE6) [A] LS2299, (1KE5) [A] LS1299, and (1KE8) [A] LS4299.
- Bottom Panel:** A "Quick Search..." input field and a checkbox for "Align selection (Pharmacophore or core molecule needed)".
- Footer:** Copyright information "LigandScout (C) 1999-2023 Inte:Ligand GmbH" and a file size indicator "88 of 152 MB".
